## 1 ABSTRACT

2 Insecticide resistance and behavioural adaptation of malaria mosquitoes affect the efficacy of long-lasting  
3 insecticide nets - currently the main tool for malaria vector control. To develop and deploy complementary,  
4 efficient and cost-effective control interventions, a good understanding of the drivers of these physiological  
5 and behavioural traits is needed. In this data-mining exercise, we modelled a set of indicators of physiological  
6 resistance to insecticide (prevalence of three target-site mutations) and behavioural resistance phenotypes  
7 (early- and late-biting, exophagy) of anopheles mosquitoes in two rural areas of West-Africa, located in  
8 Burkina Faso and Cote d'Ivoire. To this aim, we used mosquito field collections along with heterogeneous,  
9 multi-source and multi-scale environmental data. The objectives were i) to assess the small-scale spatial and  
10 temporal heterogeneity of physiological resistance to insecticide and behavioural resistance phenotypes,  
11 ii) to better understand their drivers, and iii) to assess their spatio-temporal predictability, at scales that  
12 are consistent with operational action. The explanatory variables covered a wide range of potential  
13 environmental determinants of vector resistance to insecticide or behavioural resistance phenotypes : vector  
14 control, human availability and nocturnal behaviour, macro and micro-climatic conditions, landscape, etc.  
15 The resulting models revealed many statistically significant associations, although their predictive powers  
16 were overall weak. We interpreted and discussed these associations in light of several topics of interest, such  
17 as : respective contribution of public health and agriculture in the selection of physiological resistances,  
18 biological costs associated with physiological resistances, biological mechanisms underlying biting behaviour,  
19 and impact of micro-climatic conditions on the time or place of biting. To our knowledge, our work is the first  
20 modeling insecticide resistance and feeding behaviour of malaria vectors at such fine spatial scale with such  
21 a large dataset of both mosquito and environmental data.

24 tion, statistical modeling, data mining

## Introduction

Malaria remains a major public health concern in Africa, with 234 million cases and 593 000 death over the continent in 2021 (WHO, 2022). After years of steady reduction in the disease transmission mainly due to the scale-up of vector control (VC) interventions (in particular insecticide-based tools such as long lasting insecticide nets (LLIN) and indoor residual spraying (IRS)) (Bhatt et al., 2015), progress is now stalling since 2015 (WHO, 2022). Involved in such worrying trends are a combination of biological, environmental and socio-economical factors. The mosquito biology, with the buildup of adaptive changes in the mosquito vectors populations enabling them to avoid or circumvent the lethal effects of insecticides, is most likely playing a very important contribution (Killeen, 2014). These changes are framed as vector *resistance* to insecticides. As a consequence of the widespread use of insecticides (in agriculture and public health), vector resistance has arisen rapidly in malaria vectors in many areas of Africa and above (Durnez and Coosemans, 2013; Riveron et al., 2018); and as previously indicated, is now at such level that it compromises the effectiveness of the most efficient malaria control interventions (Gatton et al., 2013; Hemingway et al., 2016; Killeen, 2014; Sokhna et al., 2013). Complementary and locally-tailored VC strategies taking into account the great diversity of vectors resistance mechanisms (see below) are therefore needed to target these vectors contributing to residual malaria transmission (Corbel and N’Guessan, 2013; Durnez and Coosemans, 2013; Hemingway et al., 2016; Moiroux, 2012; Riveron et al., 2018; Sokhna et al., 2013; WHO, 2017).

Vector resistances to insecticide are usually split into two categories : *physiological* and *behavioural* resistance (Lockwood et al., 1984; Sokhna et al., 2013). Physiological resistance refers to biochemical and morphological mechanisms (e.g. target-site modifications, metabolic resistance, cuticular thickness) that enable the mosquito to withstand the effects of insecticide despite its contact with it (Davidson, 1957). Among the physiological resistances, the target-site mutations L1014F (*kdr-w*) (Martinez-Torres et al., 1998), L1014S (*kdr-e*) (Ranson et al., 2000), and G119S (*ace-1*) (Weill et al., 2004), conferring insecticide resistance to pyrethroids (*kdr-w* and *kdr-e*) and to carbamates and organophosphates (*ace-1*), have been extensively described. behavioural resistance, on its side, refers to any modification of mosquito behaviour that facilitates avoidance or circumvention of insecticides (Carrasco et al., 2019; Gatton et al., 2013; Riveron et al., 2018). behavioural resistance of mosquitoes to insecticides can be qualitative (i.e. modifications that prevent or limit the contact with the insecticide) or quantitative (i.e. modifications that stop, limit or reduce insecticide action once contact has occurred, e.g. escaping, behavioural thermoregulation or curative self-medication) (Carrasco et al., 2019). Up-to-date, the behavioural resistance mechanisms described in the literature are mainly qualitative and consist in spatial, temporal, or trophic avoidance. In particular, in the anopheline populations, the following behavioural qualitative resistance mechanisms have been described after the scale-up of insecticide-based VC tools (Durnez and Coosemans, 2013) : i) increase of exophagic or exophilic behaviours (spatial avoidance), where mosquitoes shifted from biting or resting indoor to outdoor, ii) increase of early- or late-biting behaviours (temporal avoidance), where mosquitoes shifted from biting at night to earlier in the evening or later in the morning, iii) increase of zoophagic behaviours (trophic avoidance), where mosquitoes shifted from biting on humans to biting on animals.

To help develop and deploy complementary VC strategies that are efficient and cost-effective, a better understanding of the spatiotemporal distribution and drivers of both vector physiological resistance and feeding behaviour is needed at a local scale. We raise here a set of questions that, among others, must be explored further at local scale towards this aim :

> ***What is the respective contribution of public health and agriculture in the selection of physiological resistances in Anopheles vectors ?*** The molecular and genetic basis of physiological resistance has been widely acknowledged: under the pressure of insecticides, mutations that enable the vectors to survive are naturally selected and then spread over the generations (Labbé et al., 2017; Martinez-Torres et al., 1998). The

73 main force that governs the **selection** of a physiological mechanism of resistance in a population of insects is  
74 therefore the pressure induced by insecticide exposure. This pressure can be induced by the vector control  
75 tools, or by the runoff of pesticides used in agriculture (in many cases, the same as those used for impregnation  
76 of bed nets) into the malaria vectors breeding sites (Chandre et al., 1999; Hien et al., 2017; Reid and McKenzie,  
77 2016; Yadouleton et al., 2011). Assessing the relative contribution of these two pressures on the **selection** of  
78 resistant phenotypes is critical to further predict the relative impacts of public health and agriculture on the  
79 growth of physiological resistances and act consequently.

80  
81 > **What are the biological mechanisms underlying behavioural resistances ?** Contrary to physiological  
82 resistance, the biological mechanisms underlying behavioural resistance are still poorly known (Carrasco et al.,  
83 2019; Durnez and Coosemans, 2013; Killeen, 2014; Main et al., 2016). In particular, a pending question, having  
84 important implications for vector control, is whether behavioural shifts reflect evolutionary adaptations in  
85 response to selection pressures from vector control tools, as for physiological resistances (*constitutive resistance*)  
86 or are manifestations of pre-existing phenotypic plasticity which is triggered when facing the insecticide or  
87 in response to environmental variation that reduces human host availability (*inducible resistance*). Inducible  
88 resistance imply that vectors rapidly revert to baseline behaviours when VC interventions are lifted, whereas  
89 constitutive resistance might progressively and durably erode the effectiveness of current VC tools. Under-  
90 standing the biological mechanisms underlying behavioural resistances is therefore important to assess the  
91 long-term efficacy of insecticide-based VC interventions.

92  
93 > **Are mosquito biting behaviours modulated by local-scale environmental conditions other than insecticide-**  
94 **related ones ?** As aforementioned, the overall rise of behavioural resistances is likely caused by the widespread  
95 of insecticide-based vector control interventions. However, local environmental conditions can modulate vector  
96 behaviours at the time of foraging activity. Local climatic conditions – e.g. wind, rain, temperature, humidity,  
97 luminosity - may for example affect the timing and location of vector biting, as it has been noted in some  
98 studies (Kirby and Lindsay, 2004; Kreppel et al., 2020; Ngowo et al., 2017). Mosquitoes with natural endophagic  
99 / endophilic preferences might, for example, bite or rest outside if temperature inside is too high or humidity  
100 too low, in order to decrease their risk of desiccation-related mortality (Kreppel et al., 2020; Ngowo et al.,  
101 2017). Land cover, as well, can affect biting rhythms. It has been noted for example that distance to breeding  
102 sites may influence nocturnal host-seeking behaviour, with vectors biting on average earlier in the night in  
103 households located close to the breeding sites (Njan Nloga et al., 1993; Snow and Gilles, 2002). Assessing  
104 whether and to which extent behavioural resistance traits are influenced by local environmental (climatic or  
105 landscape) settings may help design VC tools exploiting the vulnerabilities of vectors.

106  
107 > **Are there associations between behavioural and physiological resistances ?** Physiological and be-  
108 havioural resistances may likely coexist in mosquito populations, with the first possibly influencing the second.  
109 In fact, physiologically resistant mosquitoes may, theoretically, use the recognition of insecticide-based control  
110 tool as a proxy for host presence (framed as *behavioural exploitation* (Carrasco et al., 2019)). Several studies have  
111 actually showed that the *kdr* mutation can modify the host-seeking or biting behaviour of *Anopheles* in presence  
112 of insecticide-treated net (Diop, Moiroux, et al., 2015; Diop, Chandre, et al., 2021; Porciani et al., 2017). Such  
113 behavioural exploitation could potentially lead to a better host recognition/localization and have a dramatic  
114 impact, with the control intervention having the opposite effect to the one expected. It is hence important to  
115 assess if and to which extent physiologically resistant mosquitoes exhibit different biting behaviours than their  
116 susceptible counterparts.

117  
118 > **Which adaptive strategy (physiological or behavioural resistance) arises faster ?** Understanding the  
119 relative capacity of mosquitoes to develop physiological resistance and to shift their behaviour in response to  
120 vector control is necessary to highlight where and when mitigation efforts should be prioritized (Sanou et al.,

121 2021). After introduction / re-introduction of insecticide-based tools, if vectors rapidly shift their behaviour to  
122 feed outside or at times when people are not protected by an LLIN, interventions that target such mosquitoes  
123 should be quickly deployed. In contrast, the rapid emergence of physiological resistance in vectors who  
124 continue to feed indoors and at night indicates that switching to alternative insecticide classes in indoor-based  
125 interventions may have a greater impact. Additionally, for a given environment, assessing the relative rate of  
126 selection of physiological and behavioural resistances is of direct epidemiological importance : it has been  
127 showed for example that under a scenario where LLIN and IRS are both heavily used, changes in the susceptibil-  
128 ity to insecticide is likely to have a bigger epidemiological impact than changes in biting times (Sherrard-Smith  
129 et al., 2019).

130

131 **> Are resistance rates heterogeneous at small spatiotemporal scales ?** Mosquito presence and abundance  
132 has already been found heterogeneous in space and time at fine-scale, calling for locally-tailored (species-,  
133 season-, and village-specific) control interventions (Moiroux, Bio-Bangana, et al., 2013; Moiroux, Djèntonin,  
134 et al., 2014; Taconet, Porciani, et al., 2021). However, little is known about the small-scale spatiotemporal  
135 heterogeneity of vector resistance. The potential drivers of the selection or triggering of resistant phenotypes  
136 (vector control use, land cover, micro-climate, human behaviour, etc.) are likely to vary at small spatiotem-  
137 poral scales, and so may, at the end of the line, vector resistance. As for abundances, assessing the level of  
138 heterogeneity of resistance rates in space and time is important to assess the spatiotemporal scale at which  
139 management of vector resistance should be considered.

140

141 **> To what extent can we explain and predict vector resistance and biting behaviour in space and time ?**

142 Assessing the levels of explainability and predictability of vector resistance and biting behaviour is important  
143 for both scientific and operational purposes. Towards this aim, generating statistical models linking vector  
144 resistances or biting behaviours to their potential drivers and assessing their explanatory and predictive powers  
145 can help (Shmueli, 2010; Shmueli and Koppius, 2010). High explanatory or predictive powers in the models  
146 might suggest that the conditions driving a vector to resist are well understood, and conversely, low explanatory  
147 powers might suggest that resistances are driven by factors either yet undiscovered or not included in the  
148 models. Additionally, assessing the predictability of resistances in vector populations in space and time is an  
149 important step towards mapping vector resistance at every place (e.g. village) and time (e.g. season) in the  
150 area, with such decision-support tools important to deploy the right intervention, at the right place and time  
151 (Taconet, Porciani, et al., 2021).

152

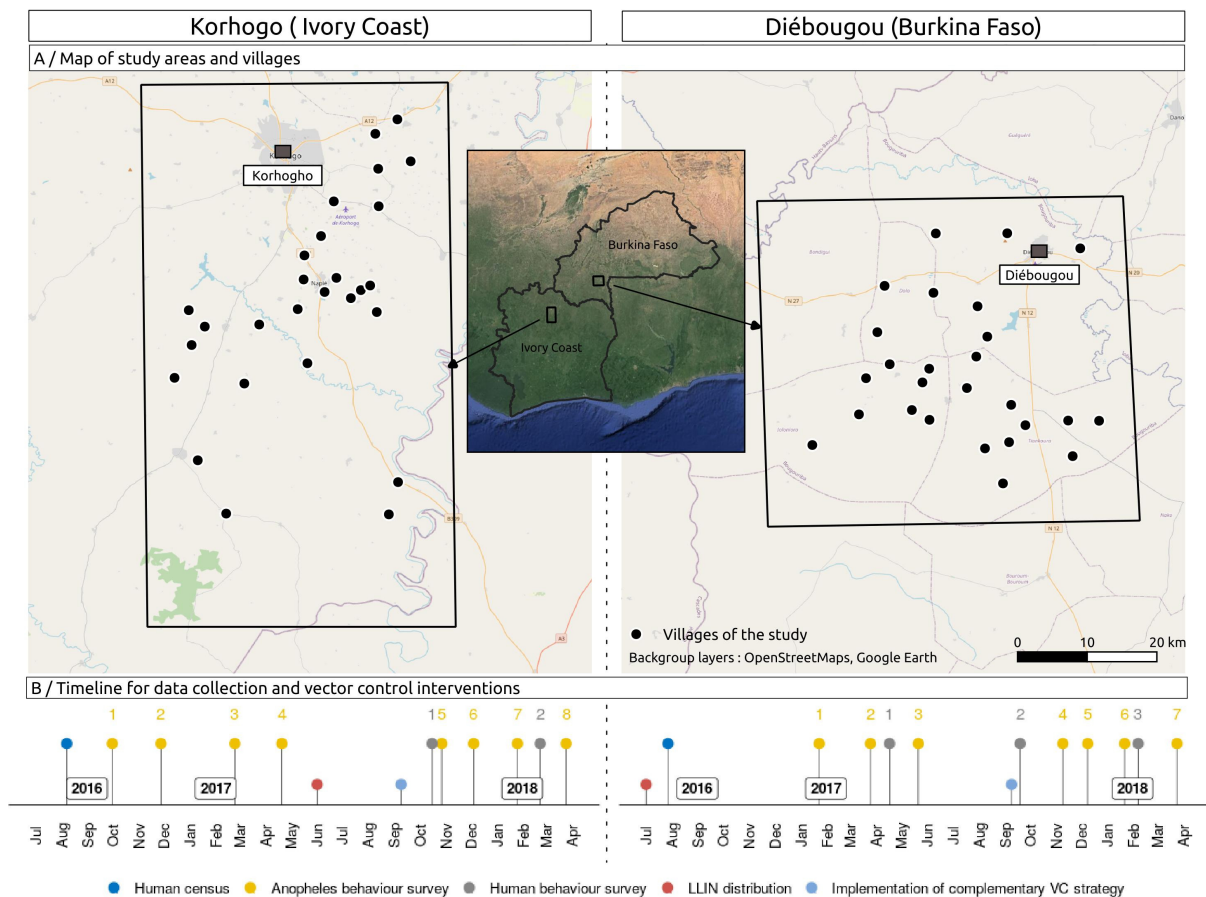

153 In this study, we used field mosquito collections and environmental data collected simultaneously in two  
154 rural areas of West-Africa to bring elements of answer to these questions for our areas. Guided by these  
155 questions, our overall objectives were i) to assess the fine-scale prevalence and spatiotemporal heterogeneity  
156 of physiological resistances and at-risk biting behaviours of malaria vectors in these areas and ii) to better  
157 understand their drivers. To do so, we modeled a set of indicators of physiological resistances and behavioural  
158 resistance phenotypes (namely *kdr-w*, *kdr-e*, *ace-1* target-site mutations, exophagy, early-biting, and late-  
159 biting) at the individual mosquito level using this fine-grained dataset and advanced statistical methods in an  
160 exploratory and holistic-inductive approach. Patterns found in the data were interpreted and discussed in  
161 light of the topics aforementioned, of importance for the management of malaria residual transmission. We  
162 concluded with a set of recommendations to manage vector resistances in our study areas.

163 **Methods**

164 **Entomological and environmental data**

165 The data used in this work were collected in the frame of the REACT project (Soma, Zogo, Somé, et al., 2020;  
 166 Zogo, DD Soma, et al., 2019). In this projet, a total of fifty-five villages, distributed in two West-African rural  
 167 areas (~ 2500 squared km each) located in the areas of Diébougou (southwestern Burkina Faso (BF)) and  
 168 Korhogo (northern Ivory Coast (IC)) were selected according to the following criteria: accessibility during the  
 169 rainy season, 200–500 inhabitants per village, and distance between two villages higher than two kilometers.  
 170 After an exhaustive census of the population in these villages at the beginning of the project, entomological  
 171 and human behaviours surveys were regularly conducted during 15 months (1.25 year) in the Diébougou  
 172 area and 18 months (1.5 year) in the Korhogo area. Vector control interventions were implemented both as  
 173 part of the project and of the national malaria control programs (see below). Figure 1 shows the study areas  
 174 and the corresponding timelines for data collection and vector control interventions. The data table available  
 175 in Moiroux, Pennetier, et al. (2023) lists the villages included in the study: names, geographic coordinates,  
 176 vector control interventions implemented in each village. Entomological data were collected in the field, and  
 177 environmental data were collated from specific devices (see below) or created from heterogeneous field and  
 178 satellite-based sources. Below is a description of the data used in our work.

179

**Figure 1.** A/ Map showing the study areas and the villages where entomological collections were performed ; B/ Timeline for vector control interventions and data collection in the villages. Each color corresponds to a different type of data collected or vector control intervention implemented. The anopheles and human behavioural surveys are numbered.

### 180 > *Anopheles* collections

181  
182 Several rounds of mosquito collections (eight in the Korhogo (IC) area, seven in the Diébougou (BF) area)  
183 were conducted in each village. The periods of the surveys span the typical climatic conditions of these tropical  
184 areas (except the peak of the rainy season - July to September) (see Additional file 1.A for the spatiotemporal  
185 trends of the meteorological conditions). Mosquitoes were collected using the Human Landing Catch (HLC)  
186 technique from 17:00 to 09:00 both indoors and outdoors at four sites per village (i.e. eight collection points)  
187 for one night during each survey. The distance between indoor and outdoor collection points was at least  
188 10 meters to minimize competition between mosquito collectors (Coffinet et al., 2009). Malaria vectors were  
189 identified using morphological keys. All individuals belonging to the *Anopheles funestus* group (in both study  
190 areas) and *Anopheles gambiae* s.l. complex (in BF) were identified to the species level using PCR. In IC, due to  
191 the very large numbers of *An. gambiae* s.l. vectors collected, a sub-sample only of these individuals (randomly  
192 selected in space and time) was identified to species. Finally, in BF, PCR assays were carried out on all the *An.*  
193 *gambiae* s.s. and *An. coluzzii* collected to detect the L1014F (*kdr-w*), the L1014S (*kdr-e*) and the G119S (*ace-1*)  
194 target-site mutations. In IC, also due to the large numbers of individuals collected, a subsample only of the  
195 \**An. gambiae* s.l.\* were genotyped for the L1014F and G119S mutations. Due to the significant risk of bias  
196 associated with the sub-sampling strategy (not all villages were sampled in all surveys), we excluded these data  
197 from the analysis. Detailed descriptions of the methods used to obtain these data are provided in Taconet,  
198 DD Soma, et al. (2023). These data were published in the Global Biodiversity Information Facility (GBIF) (D Soma  
199 et al., 2023).

### 200 > Data on weather preceding mosquito collections and during mosquito collections

201  
202  
203 Weather can impact the fitness or the activity of resistant genotypes (Kliot and Ghanim, 2012), as well as  
204 the biting behaviour of the mosquitoes (see Introduction). In this work, we recorded or retrieved weather  
205 conditions : (i) during mosquito collections (i.e. the HLC sessions), (ii) during the day of collection, and (iii)  
206 during the month preceding collection. Weather on the day of collection and during mosquito collection may  
207 impact the relative activity of each genotype and phenotypes associated with resistances. Weather during  
208 the month preceding the survey, on its side, can impact development and survival rates of both the current  
209 and parental generations of collected mosquitoes (Carnevale et al., 2009; Holstein, 1952; Townson, 1993).  
210 Regarding our outputs (prevalence of behavioural phenotypes and target-site mutations - see next section),  
211 weather during the month preceding collection may therefore impact the fitness of the studied genotypes (for  
212 target-site mutations) or possible – and unknown - genotypes associated with studied behavioural phenotypes.

213  
214 Micro-climatic conditions (temperature, relative humidity, luminosity and atmospheric pressure) were si-  
215 multaneously recorded where mosquito collections were being conducted. Instruments used to record these  
216 data were : for temperature and relative humidity : Hygro Buttons 23 Data Loggers [Proges Plus DAL0084]  
217 (temporal resolution (TR): 15 minutes) ; for luminosity : HOBO Pendant® Temperature/Light 8K Data Logger  
218 (TR: 15 minutes) ; for atmospheric pressure : Extech SD700 Data Loggers (TR : 10 minutes). Hygro and Hobo  
219 loggers were positioned both inside and outside the houses where mosquito sampling was conducted, close  
220 to the sampling positions. The barometer was positioned at the center of the village. These field data were  
221 completed with satellite or modeled data available at coarse spatial but high temporal resolutions : rain-  
222 fall (spatial resolution (SR) : ~ 11 km, TR : 30 min, source : Global Precipitation Measurement (GPM) IMERG  
223 (GSFC, 2019), wind speed (SR : ~ 28 km, TR : 1h, source : ERA5 (Hersbach et al., 2020)), apparent magnitude  
224 of the Moon (SR : 0.001 degrees, TR : 1 day, source : Institute of celestial mechanics and ephemeris calculations).

225  
226 Meteorological conditions on the day of collection and over one month preceding collection were extracted  
227 from satellite imagery. Namely, rainfall estimates were extracted from the GPM - IMERG daily Final products

228 (Center, 2019). Diurnal and nocturnal temperatures were derived from the Moderate Resolution Imaging  
229 Spectroradiometer (MODIS) daily Land Surface Temperature (LST) Terra and Aqua products (Wan et al., 2015a,b).  
230 These data were then cropped and averaged in 2-km buffer zones around each HLC collection point. From  
231 this, variables representing meteorological conditions on the day of collection and over one month preceding  
232 collection were constructed (for the latter, by averaging the 30-day time series). Detailed descriptions of the  
233 methods used to collect and process these data are provided in Taconet, Porciani, et al. (2021).

234

#### 235 > **Data on host availability and human behaviour**

236

237 The nocturnal behaviour of humans (hours inside the dwellings, hours of use of LLINs) drives host avail-  
238 ability for the mosquitoes and can therefore impact their behaviour. For instance, high LLIN use rate can  
239 drive mosquitoes to feed outside, at times when people are not protected, or on alternative sources of blood  
240 (Durnez and Coosemans, 2013). Here, human population was counted in each village, through an exhaustive  
241 census conducted at the beginning of the project. Then, several human behavioural surveys (two in IC, three in  
242 BF) were carried out in each village (see Figure 1). For each survey and village, several households (mean = 14 ,  
243 SD = 2) were randomly selected, and for each household, one to three persons in each age class (0-5 years old,  
244 6-17 years old and  $\geq$  18 years old) were selected. The head of the household was then asked, for each selected  
245 person, on the night preceding the survey : i) whether he/she used an LLIN or not, ii) the time at which he/she  
246 entered and exited his own house, and iii) the time at which he/she entered and exited his LLIN-protected  
247 sleeping space (where appropriate). Households for human behavioural surveys were independently selected  
248 from households for entomological surveys. The surveys were conducted after the distribution of the LLINs  
249 (see below), and span the typical climatic conditions of the areas. Detailed descriptions of the methods used to  
250 collect these data are provided in Soma, Zogo, Taconet, et al. (2021).

251

#### 252 > **Landscape data**

253

254 Landscape can have an impact on mosquito foraging behaviour (e.g. the distance to breeding sites can  
255 impact biting rhythms) or physiological resistance (e.g. through pesticides used in crops) (see Introduction).  
256 Digital land cover maps were produced for each study area by carrying out a Geographic Object-Based Image  
257 Analysis (Hay and Castilla, 2008) using multisource very high and high resolution satellite-derived products.  
258 From these maps, several variables were derived : the percentage of landscape occupied respectively by cotton  
259 fields, by rice fields, and by the other crops (mainly leguminous crops, millet, sorghum) in a 2 km buffer size area  
260 around each collection point ; and the distance to the nearest stream (as a proxy for the distance to **potential**  
261 **breeding sites, as shown in other studies conducted in these areas** (Taconet, Porciani, et al., 2021; Zogo, Koffi,  
262 et al., 2019)). For cotton, the variable was binarized as presence / absence of cotton cultivated due to the small  
263 range of values. In addition, the geographical location of the households was recorded, and used to derive  
264 two indices : the degree of clustering of the households in each village, and the distance from each collection  
265 point to the edge of the village. **The land cover maps along with detailed descriptions of the methods used**  
266 **to generate them are available at** Taconet, Koffi Amanan, et al. (2023) and Taconet, Dabiré, et al. (2023). **The**  
267 **methods used to compute the statistical variables from these data are detailed in** Taconet, Porciani, et al. (2021).

268

#### 269 > **Vector control**

270

271 Repeated exposure to insecticides used in vector control interventions is undoubtedly one of the most  
272 important drivers of the **selection** of resistance (see Introduction). In both Burkina Faso and Ivory Coast, LLINs  
273 have been universally distributed every 3-4 years since 2010 (PNLP, 2014a,b). In BF, a mass distribution of LLINs  
274 (PermaNet 2.0) was carried out by the National Malaria Control Program in July 2016 (i.e. 6 months before our  
275 first entomological survey). In IC, our team distributed LLINs in the villages of the project in June 2017 (i.e. height

276 months after the first entomological survey and ten months before the last one). Complementary VC tools  
277 were implemented in some of the villages in the middle of the project - namely IRS, ivermectin to peri-domestic  
278 animals (IVM), intensive Information Education and Communication to the populations (IEC), and larval control  
279 (Larv.) as part of a randomized controlled trial aiming at assessing the benefits of new, complementary VC  
280 strategies (Soma, Zogo, Somé, et al., 2020; Zogo, DD Soma, et al., 2019) (see Figure 1, and Additional file 1  
281 available online at this URL (along with the other supplementary material) : <https://doi.org/10.23708/VJEMU>  
282 (Taconet, D Soma, et al., 2023b)).

283

## 284 **Statistical analyses**

### 285 **Dependent and independant variables**

286 Six indicators of potential vector resistance to insecticides were modelled :

- 287 • three indicators of physiological resistance to insecticide : *kdr-w* mutation, *kdr-e* mutation, *ace-1* mutation,
- 288 • three indicators of behavioural resistance phenotypes : early biting, late biting, exophagy. Here, it is  
289 unknown whether changes in prevalence of studied mosquito behaviours are the result of constitutive  
290 resistances (i.e. inherited traits selected by the insecticide pressure) or of inducible resistance (that rely  
291 on phenotypic plasticity). The latter does not fit an accepted definition of insecticide resistance that  
292 rely on the inheritance property [Zalucki2017]. Therefore in the remainder of this manuscript, we  
293 will qualify the three studied phenotypes, possibly constitutive or inducible, as 'behavioural resistance  
294 phenotypes'.

295 Exophagy was defined as the probability for a host-seeking mosquito to bite outdoor (as opposed to indoor).  
296 Early biting was defined as the probability for a host-seeking mosquito to bite before 50 % of the LLIN users  
297 were declared to be under their bednet in the evening, and late biting was defined as the probability for a  
298 host-seeking mosquito to bite after 50 % of the LLIN users were declared to be out of their bednet in the  
299 morning (based on the closest - in space and time - human behaviour survey). *Kdr-w*, *kdr-e* and *ace-1* mutations  
300 were defined as the probabilities for an allele of a host-seeking mosquito to be mutated (as opposed to  
301 wild type). The statistical unit was therefore the mosquito for biting behaviour models and the allele for  
302 physiological resistance models. Dependent variables were all binary (0 = absence of resistance/mutation,  
303 1 = presence of resistance/mutation) and models outcomes were probabilities for a mosquito (resp. allele)  
304 to be resistant (resp. mutated). Each indicator was modeled separately for each main species in each study  
305 area, as determinants of resistance might be species- or site-specific (i.e. mosquitoes might respond differently  
306 to environmental variations depending on the species and study area, due to potential local chromosomal  
307 forms, adaptation, etc.) (Durnez and Coosemans, 2013; Riveron et al., 2018). As three main species were found  
308 in BF and two in IC (see Results section), a total of twenty-one dependent variables were built (exophagy : 3  
309 in BF and 2 in IC ; early biting : 3 in BF and 2 in IC ; late biting : 3 in BF and 2 in IC ; *kdr-w* : 2 in BF ; *kdr-e* : 2  
310 in BF ; *ace-1* : 2 in BF). Based on literature (see Introduction) and available data, we then built independent  
311 variables representing potential determinants of each of these resistant phenotypes. These variables are  
312 provided in Table 1. To build these variables, the source data were possibly aggregated in space or time, at  
313 varying resolutions depending on the considered dependent variable. For example, we constructed a binary  
314 variable "Rainfall during collection" (presence/absence of rainfall during the hour of collection) by summing the  
315 source data available at a 30-minutes temporal resolution and then applying a threshold (> 0 mm of rainfall  
316 = presence, otherwise absence). Replication data are available online at <https://doi.org/10.23708/LV8GEW>  
317 (Taconet, D Soma, et al., 2023a).

319

**Table 1. Independent variables built and their inclusion in the statistical models.** A cross ('x') indicates that the independent variable (in row) was used as an input in the model (in column). The source data are described in the 'Entomological and environmental data' section of the manuscript, and the binomial statistical models are described in the 'Statistical analyses' section. Some dependent or independent variables, mentioned with a \*, were available only in the BF study area.

| Independent variables (in bold : 'family' of variables and source data)                        | Statistical models (dependent variables) |              |             |                            |        |        |
|------------------------------------------------------------------------------------------------|------------------------------------------|--------------|-------------|----------------------------|--------|--------|
|                                                                                                | Behavioural resistance phenotypes †      |              |             | Physiological resistance ‡ |        |        |
|                                                                                                | Exophagy                                 | Early biting | Late biting | Kdr-w*                     | Kdr-e* | Ace-1* |
| <b>Vector control</b>                                                                          |                                          |              |             |                            |        |        |
| Vector control tool implemented in the village                                                 | x                                        | x            | x           | x                          | x      | x      |
| Time since last distribution of LLIN (months)                                                  | x                                        | x            | x           | x                          | x      | x      |

## 320 Modeling workflow

321 A graphical representation of the modeling workflow (explained below) is available in Additional figure 2. A replication  
322 R script (starting from the section 'Multivariate modeling part 1 : Explanatory model') is available online at this URL :  
323 <https://doi.org/10.23708/LV8GEW> (Taconet, D Soma, et al., 2023a).

324  
325 **Pre-processing.** First, we excluded from the modeling process those dependent variables that could hardly  
326 be modelled due to the combination of very few 'resistant' observations and extreme class imbalance (number  
327 of samples from the 'resistant' class « number of samples from the 'sensible' class). The following criteria were  
328 used for exclusion: 'resistant' class  $\leq 50$  observations &  $\leq 3\%$  of the total observations.

329  
330 Next, we implemented the modeling workflow described below for each remaining dependent variable.

331  
332 **Bivariate modeling.** We first excluded the independent variables that were poorly associated with the  
333 dependent variable (criteria for exclusion : p-value > 0.2 of a bivariate Generalized Linear binomial Mixed-effect  
334 Model (GLMM) with nested random effects at the village and collection site level). \textcolor{LimeGreen}{Next,  
335 we calculated the Pearson correlation coefficient among the retained variables and filtered-out collinear  
336 variables (correlation coefficient > 0.7) based on empirical knowledge (for instance, diurnal and nocturnal  
337 temperature over the month preceding collection were often correlated and in such case we retained nocturnal  
338 temperatures; % of the population indoor and under an LLIN in the village on the hour of collection were often  
339 correlated and in such case we retained % of the population under an LLIN).} With the set of remaining inde-  
340 pendent variables, two distinct multivariate models were built, with complementary objectives, as explained in  
341 the Box 1 below.

342  
343 **Multivariate modeling part 1 : Explanatory model.** A binomial GLMM was fitted to the data. Nested ran-  
344 dom effects were introduced in the model at the village and collection place level. Variables were deleted  
345 recursively using an automatic backward variable selection procedure based on the reduction of the Akaike  
346 Information Criterion (AIC). Variables belonging to the 'vector control' (for all resistance models) and 'crops'  
347 (for physiological resistance models only) groups were forced in the multivariate models (i.e. they were not  
348 filtered-out in the variable selection procedure) because there are strong *a priori* assumptions associated  
349 with these variables. Such variable selection procedure therefore retained all the 'vector control' and 'crops'  
350 variables (whether significantly associated or not with the dependent variable), and the additional variables  
351 that decreased the AIC of the multivariate model.

352  
353 **Multivariate modeling part 2 : Predictive model.** We additionally fitted a Random Forest (RF) model  
354 (Breiman, 2001a) to the data. The model hyperparameters were optimized using a random 5-combinations  
355 grid search (Chicco, 2017). Whenever the dependent variable was imbalanced (more than 1/3 imbalance ratio  
356 between the positive and negative class), data were up-sampled within the model resampling procedure to  
357 cope with well-known problems of machine-learning (ML) models regarding class imbalance (Tyagi and Mittal,  
358 2020).

359  
360 **Assessment of effect sizes and significance of independent variables.** To interpret the effect of each in-  
361 dependent variable in the GLMM model, we plotted, for each independent variable retained in the final  
362 model, the predicted probabilities of resistance across available values of that variable (all other things being  
363 equals) (i.e. "partial dependence plot" (PDP) (Friedman and Popescu, 2008)). For reporting and discussion  
364 in the manuscript, we kept only variables that had a p-value < 0.05 (results containing the 'full' models are  
365 provided in supplementary material, see Results section). To uncover the possible complex relationships  
366 that the RF model had learned, we generated smoothed versions of PDPs for each independent variable.  
367 However, we restricted the generation of PDPs to the following cases : i) the Area Under the Receiver Operating

368 Characteristics (AUC) (see below) of the model was > 0.6 (because model interpretation tools of ML models  
369 (e.g. PDPs) should be trusted only if the predictive power of the underlying model is good enough (Zhao  
370 and Hastie, 2021)) and ii) the range of predicted probabilities of resistance was > 0.05 (i.e. the independent  
371 variable, over its range of available values, changed the probability of resistance by at least 5 percentage points).

372

373 **Assessment of models performance.** The explanatory power of the GLMM was assessed by calculating the  
374 marginal coefficient of determination ( $R^2$ ) (Nakagawa and Schielzeth, 2013) from the observed and in-sample  
375 predicted values. Marginal  $R^2$  is a goodness-of-fit metric that measures the overall variance explained by the  
376 fixed effects in the GLMM.  $R^2$  values were interpreted according to the criteria defined by Cohen (2013) :  $R^2$   
377  $\in \{0; 0.02\}$  : very weak ;  $R^2 \in \{0.02; 0.13\}$  : weak ;  $R^2 \in \{0.13; 0.26\}$  : moderate ;  $R^2 \in \{0.26; 1\}$  : substantial.  
378 The predictive power of the RF model was assessed by leave village - out cross-validation (CV), with the Area  
379 under the ROC Curve (AUC) chosen as the performance metric. This CV strategy consisted in recursively  
380 leaving-out the observations belonging to one village of collection (i.e. the validation fold), training the model  
381 with the observations coming from the other villages (i.e. the training fold), and predicting on the left-out  
382 set of observations. We hence measured the ability of the model to predict resistance status ('resistant' or  
383 'non-resistant') on individual mosquitoes caught on new - unseen villages of collection. AUC values were  
384 interpreted according to the following criteria : AUC  $\in \{0.5; 0.6\}$  : very weak ; AUC  $\in \{0.6; 0.65\}$  : weak ; AUC  $\in$   
385  $\{0.65; 0.75\}$  : moderate ; AUC  $\in \{0.75; 1\}$  : substantial.

386

Box 1 : **What is the difference between explanatory and predictive models, and how were they used for inference in this study ?**

Explanatory and predictive models serve distinct but complementary functions in the production of scientific knowledge. In statistics, explanatory modeling refers to \*«the application of statistical models to data for testing causal hypotheses about theoretical constructs.»\* (Shmueli, 2010). Explanatory modeling, commonly used for inference in many scientific disciplines such as biology or epidemiology, is useful to test existing theories and to reach to "statistical" conclusions about causal relationships that exist at the theoretical level, e.g. : vector control significantly impacts vector resistance (or not). Explanatory modeling needs transparent and interpretable models, such as linear or logistic regression, to extract statistical information about the associations contained in the data (e.g. effect size and statistical significance) and further discuss them. On its side, predictive modeling is \*«the process of applying a statistical model or data mining algorithm aimed at making empirical predictions, and then assessing its predictive power.»\* (Shmueli, 2010). Predictive modeling requires models capable of capturing complex patterns in the data, including interactions and non-linear associations, such as \*machine learning\* models like random forests or support vector machines. Predictive analytics is typically recognised for its usefulness in practical applications, such as predicting the incidence of diseases. However, it can also play a crucial role in scientific knowledge production. For instance, predictive models can help generate new theories by capturing and revealing potentially complex, unanticipated patterns within the data. They can as well be used to evaluate the overall relevance of a theory, through the interpretation of the predictive power of the models (Shmueli and Koppius, 2010). In a "big data" context like that of this study, with large datasets containing numerous observations and variables, predictive analytics is increasingly used to support scientific theory development (Breiman, 2001b; Karpatne et al., 2017; Shmueli and Koppius, 2010).

In our study, we use explanatory modeling with GLMMs to i) test whether vector control significantly increases vector resistance, as could be expected, and ii) infer the potential determinants of vector resistance and their effect size. We use predictive modeling with RFs to i) account for potential un hypothesized, complex associations between independent and dependent variables, and ii) infer

387

the overall contribution of the independent variables to the prevalence of vector resistance, allowing at the same time to formulate hypotheses on other potential determinants.

388

## 389 **Software and libraries used**

390 The softwares used in this work were exclusively free and open source. The R programming language (R Core  
391 Team, 2018) and the R-studio environment (RStudio Team, 2020) were used as the main programming tools.  
392 The QGIS software (QGIS Development Team, 2021) and the 'ggplot2' R package (Wickham, 2016) were used  
393 to create respectively the map of the study area and the timeline for data collection. The 'glmmTMB' (Brooks  
394 et al., 2017) package was used for the bivariate modeling. The 'buildmer' package (Voeten, 2020) was used  
395 to fit the GLMM models with stepwise selection in the multivariate modeling. The 'caret' (Wing et al., 2018)  
396 and 'ranger' (Wright and Ziegler, 2017) packages were used to fit the random forest models in the multivariate  
397 modeling. The 'MLmetrics' (Yan, 2016) and 'MuMIn' (Bartoń, 2020) packages were used to calculate respectively  
398 the AUC of the RFs and the marginal  $R^2$  of the GLMMs. The 'jtools' (Long, 2020) and 'pdp' (Greenwell, 2017)  
399 packages were used to generate the partial dependence plots of respectively the GLMMs and the RFs. The  
400 'broom.mixed' (Bolker and Robinson, 2020) package was used to extract the coefficients / odd ratios, confidence  
401 intervals and p-values of the multivariate GLMMs. The 'patchwork' (Pedersen, 2019) and 'gridExtra' (Auguie,  
402 2017) packages were used to create various plot compositions. The 'tidyverse' meta-package (Wickham, 2017)  
403 was used throughout the entire analysis. A few additional R packages were used to create, tidy, and transform  
404 the data used in this work (see (Taconet, Porciani, et al., 2021)). The LibreOffice suite was used to create the  
405 tables and other plot compositions.

## 406 **Results**

### 407 **Spatio-temporal heterogeneity of vector abundance**

408 In the Korhogo area (IC), a total of 2048 human-nights of HLC was conducted. A sum of 57722 vectors belonging  
409 to the *Anopheles* genus was collected. The main species/complex found were *An. gambiae s.l.* and *An. funestus*  
410 (respectively 56267 (97% of all the *Anopheles* collected) and 714 (1%) individuals collected). Among the 56267  
411 *An. gambiae s.l.* collected, 3922 (7%) were identified to species: 3726 (95% of the individual identified to species)  
412 were *An. gambiae s.s.* and 196 (5%) were *An. coluzzii*. Hence, in the rest of this article, we will consider the  
413 *An. gambiae s.l.* collected in the Korhogo area as *An. gambiae s.s.* In the Diébougou area (BF), a total of 1512  
414 human-nights of HLC was conducted. A sum of 3056 vectors belonging to the *Anopheles* genus was collected.  
415 The main species found were *An. coluzzii*, *An. gambiae s.s.* and *An. funestus* (respectively 1321 (43% of all  
416 the *Anopheles* collected), 616 (20%) and 708 (23%) individuals collected). As expected, mosquito abundance  
417 was heterogeneous in time and space (except for *An. funestus* in IC, for which the vast majority (93 %) of  
418 the individuals was collected in the first entomological survey, and almost half of the individuals (42 %) were  
419 collected within one single village) (see additional file 1 and additional figure 3 for maps and charts of the  
420 spatiotemporal distribution of vector abundance).

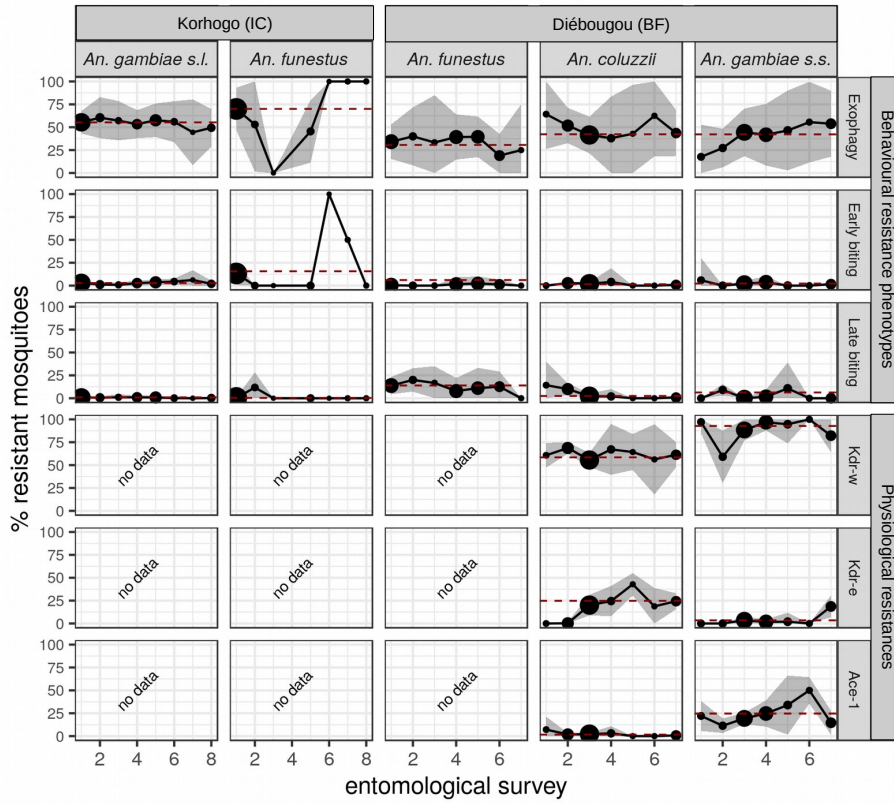

### 421 **Spatio-temporal heterogeneity of vector resistance**

422 Table 2 and Figure 2 show, respectively, global and spatiotemporal descriptive statistics on the resistances of  
423 the main vector species collected in the two areas.

424

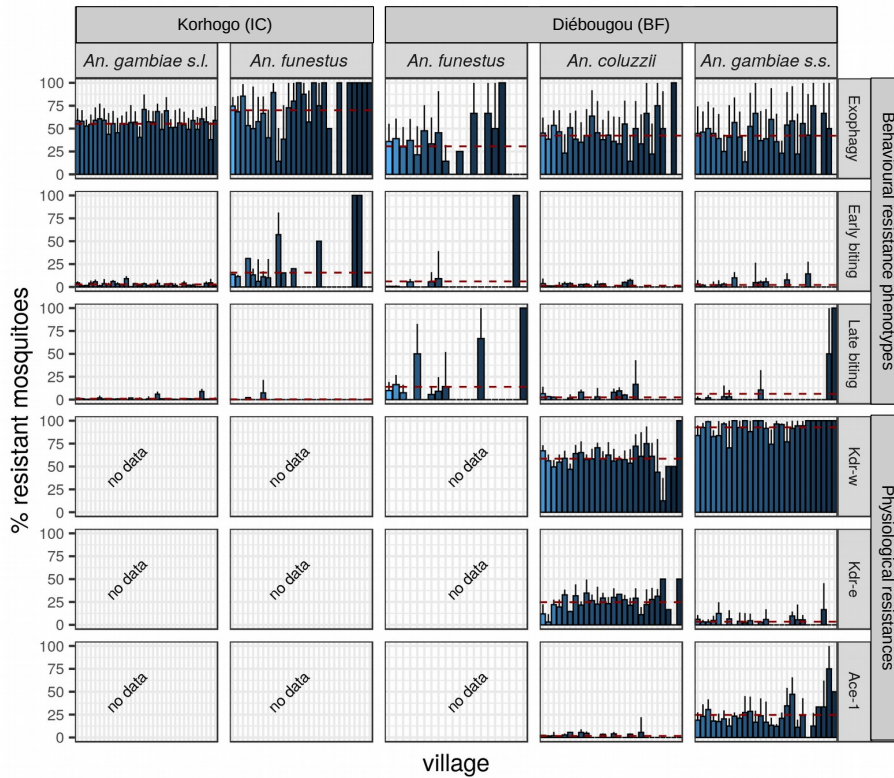

### A | Temporal distribution

1 dot = 1 entomological survey (all villages combined)  
 ribbons = spatial variability for the considered survey  
 dot sizes = % of mosquitoes collected in the considered survey over all the surveys (the biggest, the more)  
 red dashed horizontal line = overall weighted mean (all surveys considered)

### B | Spatial distribution

1 bar = 1 village (all entomological surveys combined)  
 error bars = temporal variability for the considered village  
 bar colors = % of mosquitoes collected in the considered village over all the villages (the brighter, the more)  
 red dashed horizontal line = overall weighted mean (all villages considered)

**Figure 2. (Previous page) Spatio-temporal distributions of the physiological resistances and behavioural resistance phenotypes of the main vector species collected (panel A : temporal distribution, panel B : spatial distribution).** For behavioural resistance phenotypes, the y-axis represents the percentage of mosquitoes with resistant phenotypes for the considered survey / village. For physiological resistances, the y-axis represents the allele frequency of the considered mutation for the considered survey / village. Confidence intervals (A : ribbons, B : lineranges) provide indicators of variability of the resistance indicator (A : mean  $\pm$  standard deviation of the resistance indicator calculated at the village level for the considered entomological survey ; B : mean  $\pm$  standard deviation of the resistance indicator calculated at the entomological survey level for the considered village). To avoid excessive consideration of small sample sizes, the total number of mosquito collected was represented graphically using the size of dots (A) or the color of the bars (B).

**Table 2. (below) Descriptive statistics for the physiological resistances and behavioural resistance phenotypes of the main vector species collected.**

| Resistance indicator | Study area | Species                 | n° collected | n° resistant | % resistant | Temporal confidence interval & range | Spatial confidence interval & range |
|----------------------|------------|-------------------------|--------------|--------------|-------------|--------------------------------------|-------------------------------------|
| Exophagy             | Korhogo    | <i>An. gambiae s.l.</i> | 56267        | 31295        | 56 %        | $\pm 2 \%$ (44 – 60)                 | $\pm 7 \%$ (38 – 71)                |
|                      |            | <i>An. funestus</i>     | 714          | 493          | 69 %        | $\pm 7 \%$ (0 – 100)                 | $\pm 16 \%$ (0 – 100)               |
|                      | Diébougou  | <i>An. coluzzii</i>     | 1321         | 577          | 44 %        | $\pm 5 \%$ (38 – 64)                 | $\pm 9 \%$ (0 – 100)                |
|                      |            | <i>An. gambiae s.s.</i> | 616          | 268          | 44 %        | $\pm 7 \%$ (18 – 56)                 | $\pm 12 \%$ (0 – 75)                |
|                      |            | <i>An. funestus</i>     | 708          | 250          | 35 %        | $\pm 6 \%$ (19 – 40)                 | $\pm 8 \%$ (0 – 100)                |
| Early biting         | Korhogo    | <i>An. gambiae s.l.</i> | 56267        | 1670         | 3 %         | $\pm 1 \%$ (1 – 6)                   | $\pm 2 \%$ (0 – 10)                 |
|                      |            | <i>An. funestus</i>     | 714          | 92           | 13 %        | $\pm 6 \%$ (0 – 100)                 | $\pm 12 \%$ (0 – 100)               |
|                      | Diébougou  | <i>An. coluzzii</i>     | 1321         | 28           | 2 %         | $\pm 1 \%$ (0 – 4)                   | $\pm 2 \%$ (0 – 75)                 |
|                      |            | <i>An. gambiae s.s.</i> | 616          | 19           | 3 %         | $\pm 1 \%$ (0 – 6)                   | $\pm 3 \%$ (0 – 14)                 |
|                      |            | <i>An. funestus</i>     | 708          | 9            | 1 %         | $\pm 1 \%$ (0 – 2)                   | $\pm 4 \%$ (0 – 100)                |
| Late biting          | Korhogo    | <i>An. gambiae s.l.</i> | 56267        | 499          | 1 %         | $\pm 0 \%$ (0 – 1)                   | $\pm 1 \%$ (0 – 9)                  |
|                      |            | <i>An. funestus</i>     | 714          | 4            | 1 %         | $\pm 1 \%$ (0 – 12)                  | $\pm 1 \%$ (0 – 7)                  |
|                      | Diebougou  | <i>An. coluzzii</i>     | 1321         | 46           | 3 %         | $\pm 3 \%$ (0 – 14)                  | $\pm 3 \%$ (0 – 14)                 |
|                      |            | <i>An. gambiae s.s.</i> | 616          | 8            | 1 %         | $\pm 3 \%$ (0 – 11)                  | $\pm 5 \%$ (0 – 100)                |
|                      |            | <i>An. funestus</i>     | 708          | 82           | 12 %        | $\pm 3 \%$ (0 – 22)                  | $\pm 10 \%$ (0 – 100)               |
| Kdr-w mutation       |            | <i>An. coluzzii</i>     | 1321         | NA           | 59 %        | $\pm 5 \%$ (55 – 69)                 | $\pm 8 \%$ (12 – 100)               |
|                      |            | <i>An. gambiae s.s.</i> | 616          | NA           | 90 %        | $\pm 8 \%$ (59 – 100)                | $\pm 9 \%$ (68 – 100)               |
| Kdr-e mutation       | Diébougou  | <i>An. coluzzii</i>     | 1321         | NA           | 17 %        | $\pm 8 \%$ (0 – 43)                  | $\pm 10 \%$ (0 – 50)                |
|                      |            | <i>An. gambiae s.s.</i> | 616          | NA           | 4 %         | $\pm 4 \%$ (0 – 19)                  | $\pm 4 \%$ (0 – 17)                 |
| Ace-1 mutation       |            | <i>An. coluzzii</i>     | 1321         | NA           | 2 %         | $\pm 1 \%$ (0 – 7)                   | $\pm 1 \%$ (0 – 6)                  |
|                      |            | <i>An. gambiae s.s.</i> | 616          | NA           | 21 %        | $\pm 6 \%$ (11 – 50)                 | $\pm 8 \%$ (0 – 75)                 |

*Descriptive statistics for the physiological resistances and behavioural resistance phenotypes of the main vector species collected, by area of interest. The columns 'Temporal confidence interval and range' and 'Spatial confidence interval and range' provide indicators of the variability and range of resistance around the overall mean (percentage resistant) respectively in time (i.e. variability between the entomological surveys) and space (i.e. variability between the villages). Format of these columns: standard deviation (minimum – maximum). Computation of standard deviation : to take into account the uneven sample size between entomological surveys (resp. villages) (i.e. to avoid excessive consideration of small / very small sample size), confidence intervals for temporal (resp. spatial) variability were extracted by first calculating the resistance indicator for each entomological survey (resp. village) and then computing the standard deviation weighted by the number of mosquitoes collected in each entomological survey (resp. village).*

**Exophagy rates.** In the Korhogo area (IC), the overall exophagy rate (% of bites received outdoor) was 56 % for *An. gambiae s.l.* and 69 % for *An. funestus*. The exophagy rate of *An. gambiae s.l.* varied little, both amongst the entomological surveys and the villages (Temporal Standard Deviation (TSD) (see legend of Table 2 for definition) =  $\pm 2 \%$ , Spatial Standard Deviation (SSD) (see legend of Table 2 for definition) =  $\pm 7 \%$ ). The

430 exophagy rate of *An. funestus* was more heterogeneously distributed in time and space (TSD =  $\pm 7\%$ , SSD =  $\pm$   
431 16%). In the Diébougou area (BF), the overall exophagy rate was 44% for *An. coluzzii*, 44% for *An. gambiae*  
432 s.s. and 35% for *An. funestus*. For the three species, the exophagy rate varied quite sensibly among the entomological surveys (TSD =  $\pm 5\%$ ,  $\pm 7\%$ ,  $\pm 6\%$  respectively) and the villages (SSD =  $\pm 9\%$ ,  $\pm 12\%$ ,  $\pm 8\%$  respectively).  
433

434

435 **Early and late biting rates.** In the Korhogo area (IC), the early biting rate (i.e. % of bites received before 50%  
436 of the LLIN users were declared to be under their bednet at night) was 3% for *An. gambiae s.l.* and 13% for *An.*  
437 *funestus*. The early biting rate was overall stable among the surveys and villages for *An. gambiae s.l.* (TSD =  $\pm$   
438 1%, SSD =  $\pm 2\%$ ) and was more heterogeneously distributed for *An. funestus* (TSD =  $\pm 6\%$ , SSD =  $\pm 12\%$ ). The  
439 late biting rate (i.e. % of bites received after 50% of the LLIN users were declared to be out of their bednet  
440 in the morning) was lower than the early biting rate : 1% for both *An. gambiae s.l.* and *An. funestus* (only 4  
441 late-bites for *An. funestus*) and was overall stable among the surveys and villages (TSD =  $\pm 0\%$  and SSD =  $\pm 1\%$   
442 for *An. gambiae s.l.*). In the Diébougou area (BF), the early biting rate was respectively 2%, 3% and 1% for *An.*  
443 *coluzzii*, *An. gambiae s.s.* and *An. funestus*. The early biting rate was overall stable among the surveys (TSD =  $\pm$   
444 1% for the three species) and to some extent more heterogeneous among the villages (SSD =  $\pm 2\%$ ,  $\pm 3\%$ ,  $\pm$   
445 4% respectively). The late biting rate was respectively 3%, 1% and 12% for *An. coluzzii*, *An. gambiae s.s.* and  
446 *An. funestus*. Late biting rates were more heterogeneously distributed than early biting rates, both among the  
447 surveys (TSD =  $\pm 3\%$  for the three species) and villages (SSD =  $\pm 3\%$ ,  $\pm 5\%$ ,  $\pm 10\%$  respectively).  
448

448

449 **Allele frequencies of *kdr-e*, *kdr-w*, *ace-1* mutations.** In the BF area, the allele frequency of the *kdr-w*  
450 mutation was 90% for *An. gambiae s.s.* and 59% for *An. coluzzii*. It varied to some extent among the surveys and  
451 villages (for *An. gambiae s.s.* : TSD = 8%, SSD = 9% ; for *An. coluzzii* : TSD = 5%, SSD = 8%). The allele frequency  
452 of the *kdr-e* mutation was 4% for *An. gambiae s.s.* and 17% for *An. coluzzii*. For *An. gambiae s.s.*, it remained low  
453 among the surveys and villages (TSD = SSD = 4%) and for *An. coluzzii*, it varied more sensibly (TSD = 8%, SSD =  
454 10%). The allele frequency of the *ace-1* mutation was 21% for *An. gambiae s.s.* and 2% for *An. coluzzii*. For *An.*  
455 *gambiae s.s.*, it varied sensibly among the surveys and villages (TSD = 6%, SSD = 8%), and for *An. coluzzii* it was  
456 overall stably low (TSD = SSD = 1%).

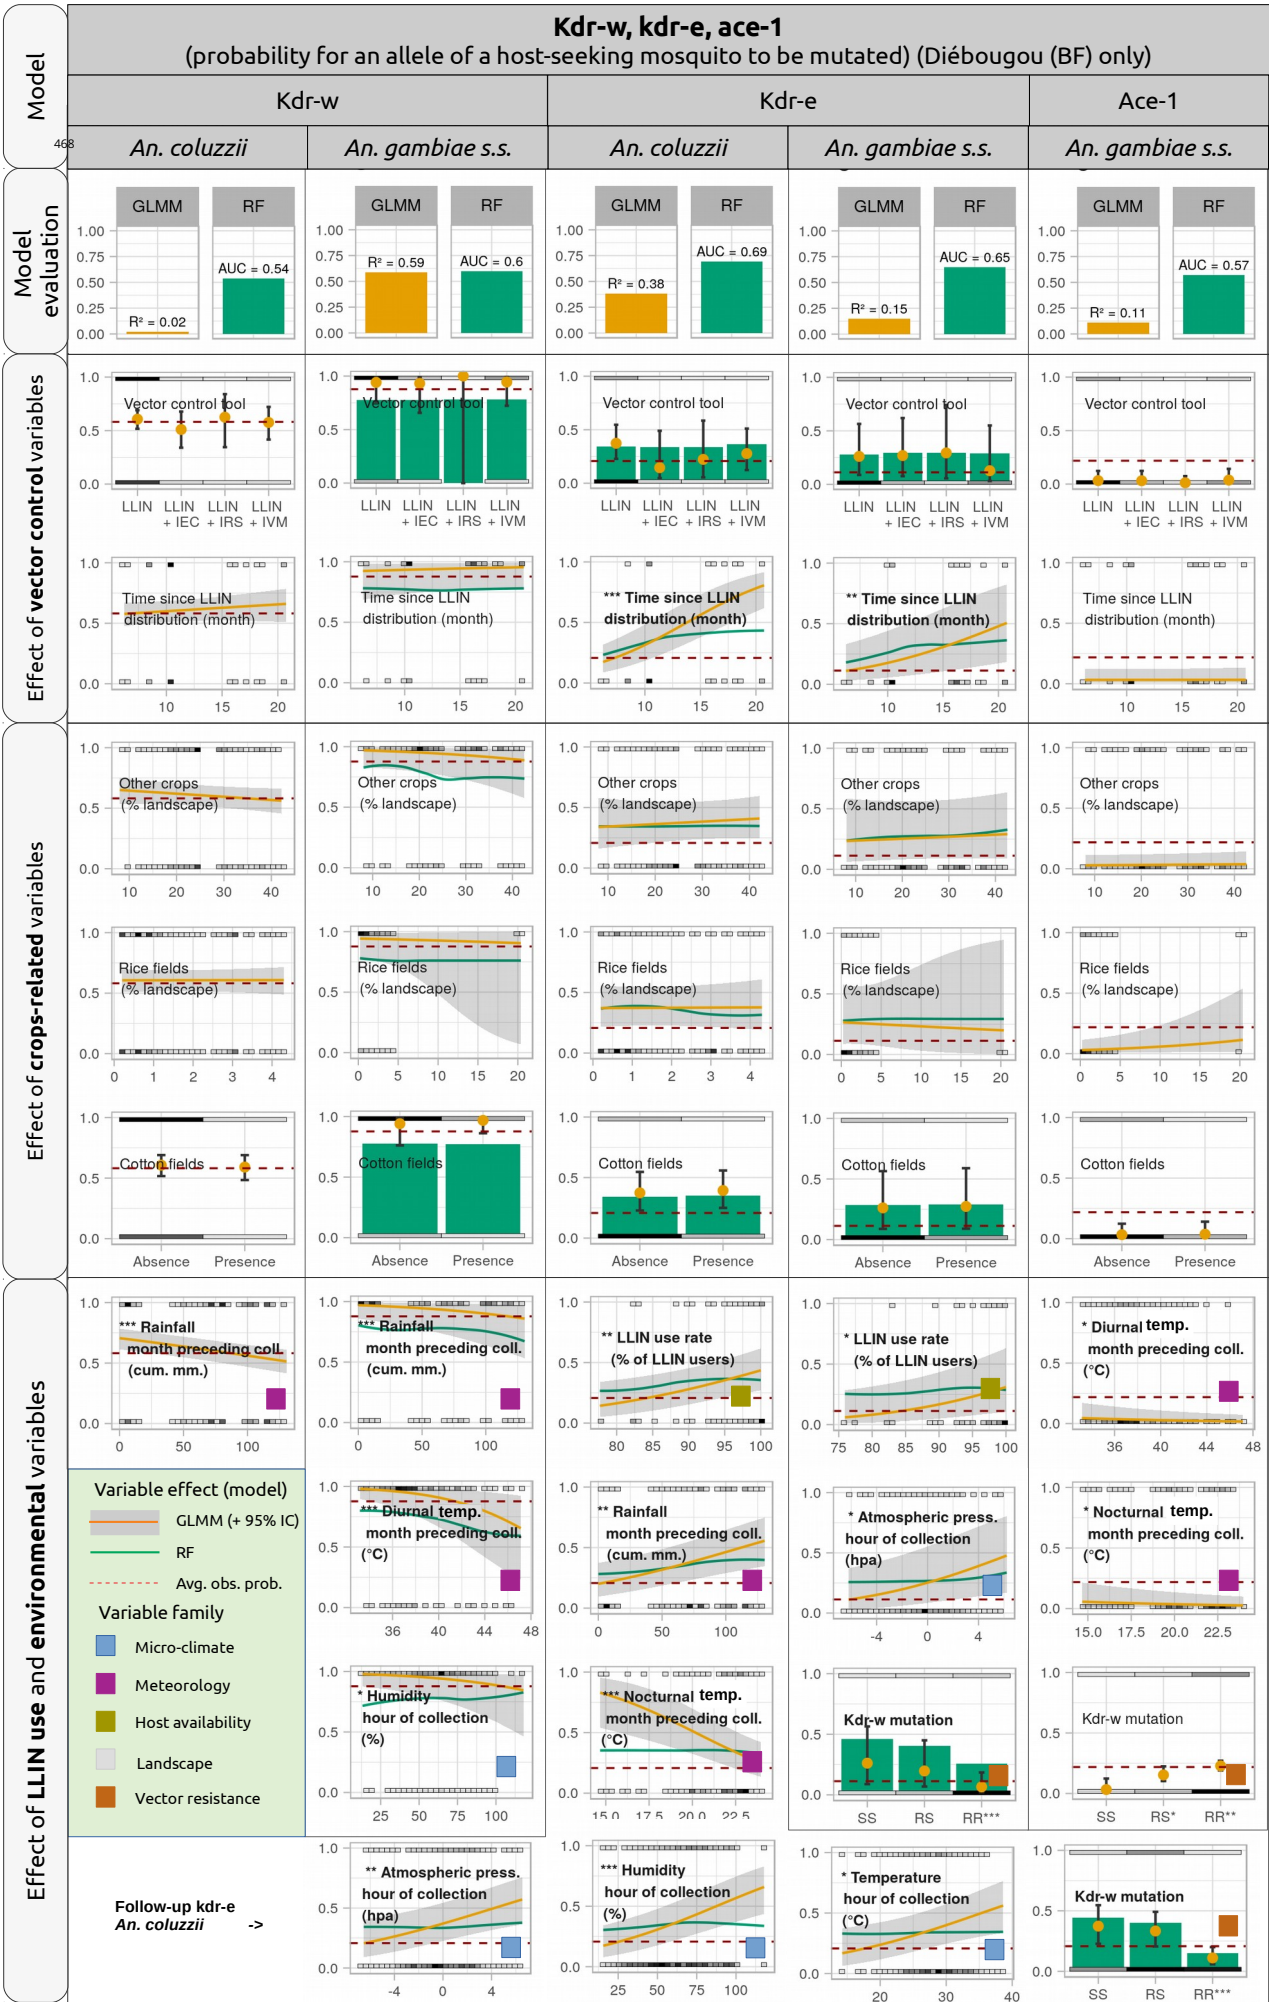

## 457 **Dependent variables excluded from the modeling process**

458 Seven of the original twenty-one dependent variables were excluded before statistical modeling due to the  
459 very small size of their 'resistant' class (see Table 2) :

- 460 • early-biting in BF for the three species,
- 461 • late-biting in BF for *An. coluzzii* and *An. gambiae s.s.*,
- 462 • late-biting in IC for *An. funestus*,
- 463 • *ace-1* in BF for *An. coluzzii*.

## 464 **Associations between physiological resistance and environmental variables**

465 For the remaining five models of physiological resistance in the Diébougou area (BF), Figure 3 shows the  
466 PDPs of the independent variables retained in the modeling workflow. For the GLMMs, numerical values of  
467 odd-ratios, 95% confidence intervals, and p-values are provided in Additional file 4.

**Figure 3. (Previous page) Results of the statistical models of probability of physiological resistance in the malaria vectors.** For each model, the top plot shows the explanatory power ( $R^2$ ) and predictive power (AUC) of respectively the GLMM and the RF model. The other plots show the predicted probabilities of collecting a resistant vector across available values of each independent variable, holding everything else in the model equal (yellow line : probability predicted by the GLMM model ; green line : probability predicted by the RF model). *Non-significant variables ( $p$ -value > 0.05) are not presented.* Short *methodological* reminder : vector control and crops variables were forced-in, and the other variables were retained only if they improved the AIC of the model. In addition, for the GLMM models, the other variables were plotted only if their  $p$ -value was < 0.05. For the RF models, the predicted probability (i.e. green line) was plotted only if the AUC of the model was > 0.6 and the range of predicted probabilities of resistance for the considered variable was > 0.05. In these plots, the y-axis represents the probability for an allele to be resistant. The red horizontal dashed line represents the overall rate of resistance (see Table 2). The  $p$ -values of the GLMMs are indicated through the stars : \* :  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ . *The coloured squared at the bottom-right represents the 'family' the variables belongs to (one color for each family, see legend inside the light green frame placed on the left hand side of the plot).* The grey squares distributed along the x-axis at the top and bottom of each plot represent the measured values available in the data (the darker the square, the more the number of observations) (NB : for atmospheric pressure, the values in the x-axis are centered around the mean)

469 **Associations with variables encoding vector control interventions.** No statistically significant association  
 470 was found between the likelihood of collecting an *Anopheles* carrying any of the target-site mutations and the  
 471 type of VC intervention (LLIN + complementary tool compared to LLIN only) within the time frame of the study.  
 472 However, the likelihood of collecting a host-seeking *An. gambiae* s.s. or *An. coluzzii* carrying a resistant *kdr-e*  
 473 allele increased with the time since LLIN distribution, and as well with the % of users of LLINs in the village  
 474 population. *Noteworthy, for both species the random forest models predicted a significant linear increase in*  
 475 *the 12 first months after the distribution, and a slowdown in the increase from the 12th to the 21th month*  
 476 *after LLIN distribution.* Regarding the others target-site mutations (*kdr-w* or *ace-1*), the likelihood of collecting a  
 477 host-seeking *Anopheles* carrying them did not increase with the time since LLIN distribution.

478  
 479 **Associations with variables encoding crops.** No statistically significant association was found between the  
 480 likelihood of collecting a host-seeking *Anopheles* carrying any of the target-site mutations and the % of land-  
 481 scape occupied by crop fields (cotton, rice, or other crops) in a 2 km-wide buffer area around the collection point.

482  
 483 **Associations with variables encoding micro-climate at the time (hour) of foraging activity.** Positive asso-  
 484 ciations were found between the likelihood of collecting a host-seeking *An. coluzzii* carrying the *kdr-e* mutation  
 485 and atmospheric pressure, humidity and temperature at the time of collection, as well as that of collecting an  
 486 *An. gambiae* s.s. carrying the *kdr-e* mutation and atmospheric pressure at the time of collection. A negative  
 487 association was found between the likelihood of collecting a host-seeking *An. gambiae* s.s. carrying the *kdr-w*  
 488 mutation and humidity at the time of collection.

489  
 490 **Associations with variables encoding meteorological conditions during the month preceding collection.**  
 491 Negative associations were found between the likelihood of collecting a host-seeking : *An. coluzzii* carrying the  
 492 *kdr-w* mutation and cumulated rainfall, *An. gambiae* s.s. carrying the *kdr-w* mutation and both cum. rainfall and  
 493 mean diurnal temperatures, *An. coluzzii* carrying the *kdr-e* mutation and mean nocturnal temperatures, *An.*  
 494 *gambiae* s.s. carrying *ace-1* mutation and both mean diurnal and nocturnal temperatures during the month  
 495 preceding collection. A positive association was found between the likelihood of collecting a host-seeking *An.*  
 496 *coluzzii* carrying the *kdr-e* mutation and cumulated rainfall.

497  
 498 \*\*\*Association with variables encoding genotype for other insecticide resistance target-site mutations.\*\*\*  
 499 The likelihood of collecting a host-seeking \**An. gambiae* s.s.\* or \**An. coluzzii*\* carrying a resistant *kdr-e* allele

500 was negatively associated with the number of mutated *kdr-w* alleles in the collected mosquito. Conversely,  
501 the likelihood of collecting a host-seeking *An. gambiae* s.s. carrying a resistant *Ace-1* allele was higher in  
502 individuals also carrying *kdr-w* mutated alleles.

### 503 **Associations between behavioural resistance phenotypes and environmental vari-** 504 **ables**

505 For the remaining nine models of behavioural resistance phenotypes, Figure 4 shows the PDPs of the inde-  
506 pendent variables retained in the modeling workflow. For the GLMMs, numerical values of odd-ratios, 95%  
507 confidence intervals and p-values are provided in Additional file 4.

Model

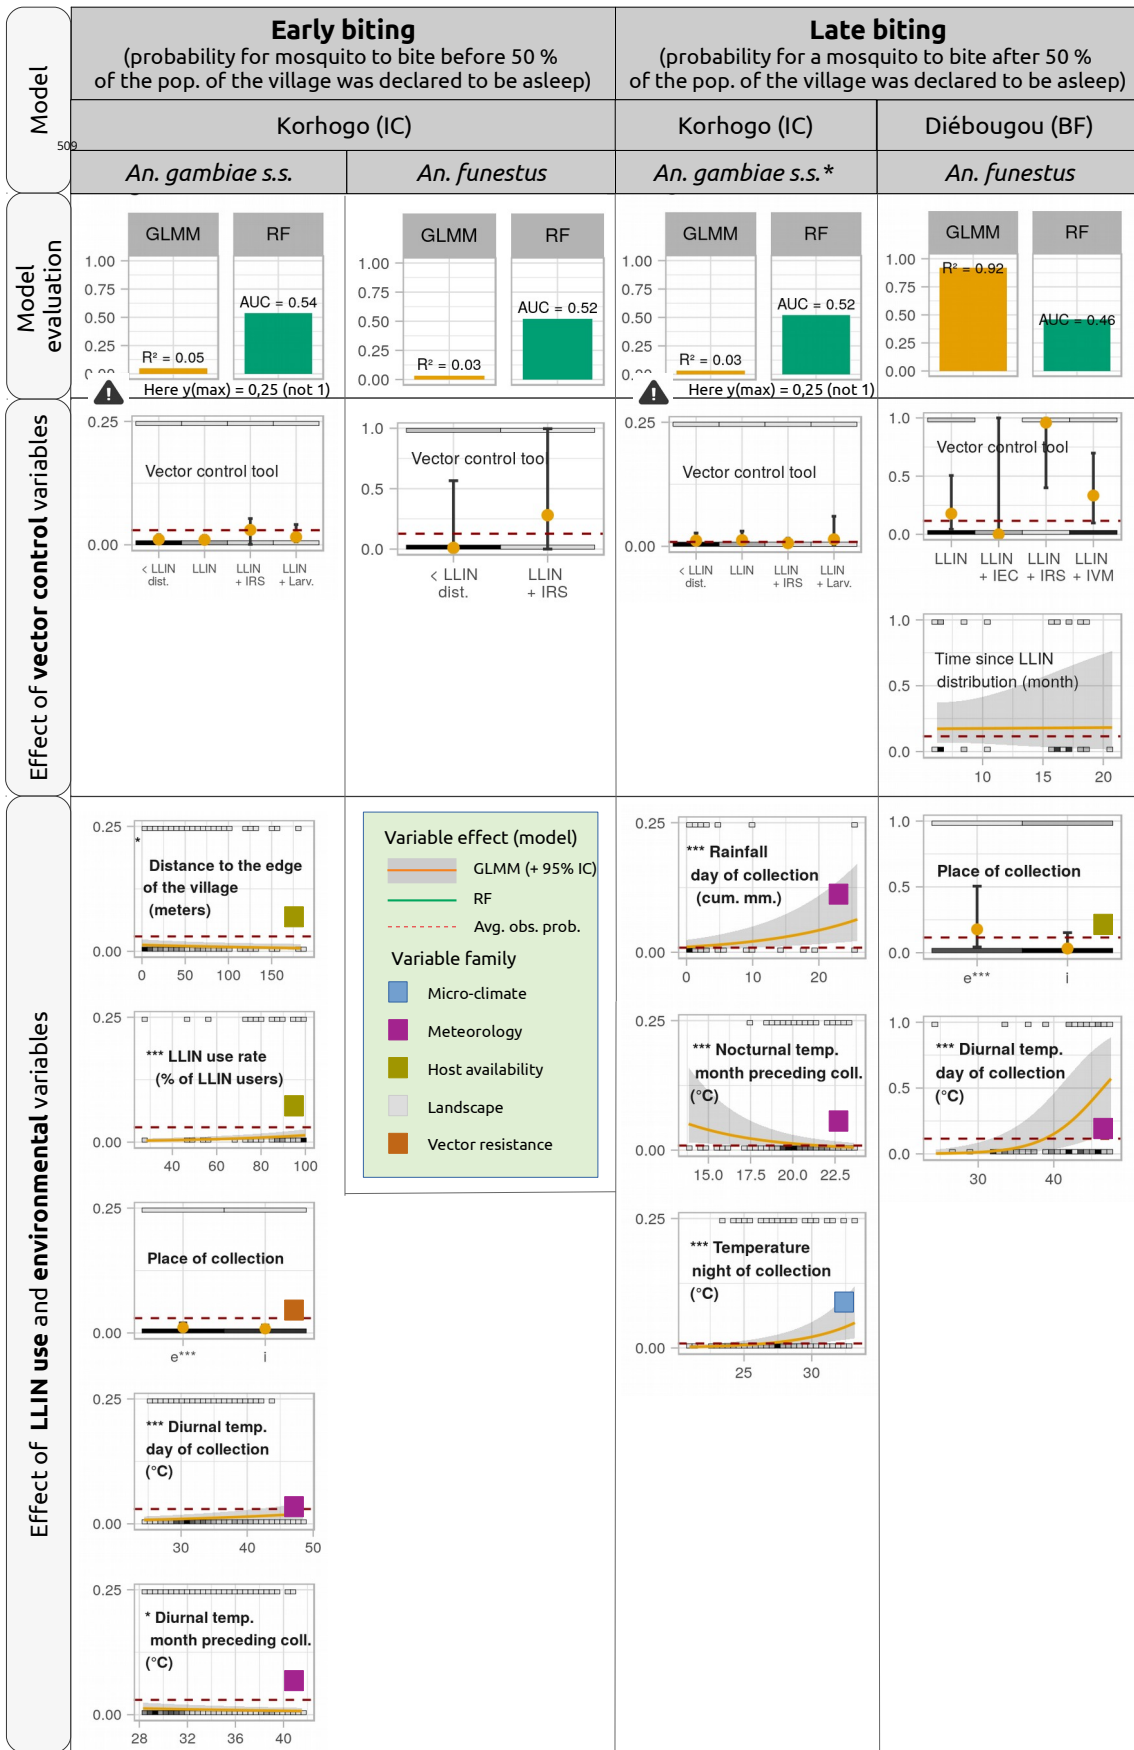

Model evaluation

Effect of vector control variables

Effect of LLIN use and environmental variables

**Figure 4. (Previous page) Results of the statistical models of probability of behavioural resistance phenotypes in the malaria vectors.** For each model, the top plot shows the explanatory power ( $R^2$ ) and predictive power (AUC) of respectively the GLMM and the RF model. The other plots show the predicted probabilities of collecting a resistant vector across available values of each independent variable, holding everything else in the model equal (yellow line : probability predicted by the GLMM model ; green line : probability predicted by the RF model). *Non-significant variables (p-value > 0.05) are not presented.* Short *methodological* reminder : vector control variables were forced-in, and the other variables were retained only if they improved the AIC of the model. In addition, other variables were plotted only if their p-value was < 0.05. For the RF models, the predicted probability (i.e. green line) was plotted only if the AUC of the model was > 0.6 and the range of predicted probabilities of resistance for the considered variable was > 0.05. In these plots, the y-axis represents the probability for a mosquito to be resistant. The red horizontal dashed line represents the overall rate of resistance (see Table 2). The p-values of the GLMMs are indicated through the stars \* :  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ . *The coloured squared at the bottom-right represents the 'family' the variable belongs to (one color for each family, see legend inside the light green frame placed on the left hand side of the plot).* The grey squares distributed along the x-axis at the top and bottom of each plot represent the measured values available in the data (the darker the square, the more the number of observations) (NB : for atmospheric pressure, the values in the x-axis are centered around the mean).

510 **Associations with variables encoding vector control interventions.** No statistically significant association  
 511 was found between the likelihood of collecting an exophagic, early- or late- biting *Anopheles* and neither the  
 512 type of VC intervention (LLIN + complementary tool compared to LLIN only) nor the time since LLIN distribution  
 513 within the time frame of the study.

514

515 **Associations with variables encoding host availability.** In the Korhogo area (IC), the likelihood of exophagy  
 516 of *An. gambiae* s.s. slightly increased with the % of the population under an LLIN at the time of collection. The  
 517 likelihood of early-biting of *An. gambiae* s.s. increased with the % of users of LLINs in the village population. In  
 518 the Diébougou (BF) area, the likelihood of exophagy of *An. funestus* increased with the % of the population  
 519 under an LLIN at the time of collection.

520

521 **Associations with variables encoding landscape.** In the Korhogo area (IC), the likelihood of exophagy of  
 522 *An. funestus* increased with increasing distance to the edge of the village. The likelihood of early-biting of *An.*  
 523 *gambiae* s.s. decreased with increasing distance to the edge of the village. In the Diébougou (BF) area, the  
 524 likelihood of exophagy of *An. coluzzii* increased with increasing distance to the nearest stream.

525

526 **Associations with variables encoding micro-climate at the time (hour) of foraging activity.** In the Korhogo  
 527 area (IC), the likelihood of exophagy of *An. gambiae* s.s. decreased when humidity indoors increased and when  
 528 humidity got relatively higher indoors compared to outdoors. In addition, it increased when luminosity got  
 529 relatively higher indoors compared to outdoors. In the Diébougou area (BF), the likelihood of exophagy of *An.*  
 530 *funestus* increased when temperature or humidity got relatively higher indoors compared to outdoors.

531

532 **Associations with variables encoding meteorological conditions on the day or night of collection.** Positive  
 533 associations were found between the likelihood of : exophagy of *An. coluzzii* and rainfall (BF area), early-biting  
 534 of *An. gambiae* s.s. and temperature (IC area), late-biting of *An. gambiae* s.s. and both rainfall and temperature  
 535 (IC area), late-biting of *An. funestus* and temperature (BF area). A negative association was found between the  
 536 likelihood of exophagy of *An. gambiae* s.s. and rainfall (IC area).

537

538 **Associations with variables encoding meteorological conditions during the month preceding collection.**  
 539 Negative associations were found between the likelihood of : exophagy of *An. gambiae* s.s. and both cumulated  
 540 rainfall and mean diurnal temperatures (IC area), exophagy of *An. coluzzii* and mean nocturnal temperatures

541 (BF area), late biting of *An. gambiae* s.s. and mean nocturnal temperature (IC area). A positive association was  
542 found between the likelihood of exophagy of *An. gambiae* s.s. and mean nocturnal temperatures (BF area).

543

544 **Associations with variables encoding physiological resistances.** As a reminder, the genotypes for the  
545 target-site mutations of individual collected mosquitoes were introduced as independent variables in the  
546 behavioural resistance phenotypes models in the Diébougou area (BF). Here, these variables were not retained  
547 in the variable selection procedure, i.e. no statistically significant association was found between any of the  
548 behavioural resistance indicator and *kdr-w*, *kdr-e*, or *ace-1* mutations.

## 549 Explanatory and predictive power of the statistical models

550 Additional figure 5 provides boxplots of observed resistance status vs. predicted probabilities by each model.

551

552 **Exophagy.** For the models of exophagy, the explanatory power of the GLMM models was : 'very weak' for *An.*  
553 *gambiae* s.s. in the Korhogo area (IC), 'moderate' for *An. funestus* in the Korhogo area (IC), 'weak' for *An. funestus*,  
554 *An. coluzzii* and *An. gambiae* s.s. in the Diébougou area (BF). The predictive power of the RF models of exophagy  
555 was 'very weak' for all the species in the two study areas.

556

557 **Early and late biting.** For the models of early biting, the explanatory power of the GLMM models was 'weak'  
558 for both *An. gambiae* s.s. and *An. funestus* in the Korhogo area (IC). For the models of late biting, the explanatory  
559 power of the GLMM was 'weak' for *An. gambiae* s.s. in the Korhogo area (IC) and 'substantial' for *An. funestus* in  
560 the Diébougou area (BF). The predictive power of the RF models of early and late biting was 'very weak' for all  
561 species in the two study areas, except for the model of late biting of *An. gambiae* s.s. in the Korhogo area (IC)  
562 for which it was 'weak'.

563

564 ***Kdr-w*, *kdr-e*, *ace-1*.** For the *kdr-w* mutation in the Diébougou area (BF), the explanatory power of the GLMM  
565 models was 'weak' for *An. coluzzii* and 'substantial' for *An. gambiae* s.s. ; and the predictive power of the RF  
566 models was 'weak' for *An. coluzzii* and 'moderate' for *An. gambiae* s.s. For the *kdr-e* mutation in the Diébougou  
567 area (BF), the explanatory power of the GLMM models was 'substantial' for both *An. coluzzii* and *An. gambiae* s.s.  
568 ; and the predictive power of the RF models was 'moderate' for *An. coluzzii* and 'weak' for *An. gambiae* s.s. For  
569 the *ace-1* mutation in the Diébougou area (BF), the explanatory power of the GLMM models was 'weak' for *An.*  
570 *gambiae* s.s. ; and the predictive power of the RF model was 'very weak'.

## 571 Discussion

572 In this data mining exercise, we studied indicators of physiological and behavioural resistance phenotypes  
573 of several malaria vectors in rural West-Africa at a fine spatial scale (approximately the extent of a health  
574 district), using longitudinal data collected in two areas belonging to two different countries, respectively 27  
575 and 28 villages per area, and across 1.25 to 1.5 year. The objectives were to describe the spatial and temporal  
576 heterogeneity of vector resistance, and to better understand their drivers, at scales that are consistent with  
577 operational action. To our knowledge, our work is the first studying the heterogeneity of vector resistance at  
578 such fine spatial scale with such a large dataset of mosquito collection and potential drivers of resistance. In  
579 this discussion, we first use our results to provide elements of answers to the questions raised in introduction  
580 of this article. We then discuss some implications of the findings for the management of vector resistance in  
581 our areas.

## 582 **Physiological resistances: potential drivers and spatiotemporal heterogeneity**

583 The main drivers of physiological resistances are insecticides, used either in public health for vector control or  
584 in agriculture (see Introduction). In this study, we found that the probability of collecting a host-seeking *An.*  
585 *gambiae* s.s. or *An. coluzzii* in the Diébougou area carrying a *kdr-e* resistant allele significantly increased with  
586 both the time since LLIN distribution (up to 12 months after distribution) and the % of LLIN users in the village  
587 population. PermaNet 2.0 LLINs have been shown to retain their insecticidal efficacy under field conditions for  
588 at least one year after distribution (Djènontin, Alfa, et al., 2023; Kayedi et al., 2017; Kilian et al., 2008; Tan et al.,  
589 2016), exerting high selective pressure on vectors over this period at least. In contrast, there was no significant  
590 association between any of the target-site mutations and any of the crop-related variable. Altogether, This  
591 could indicate that **within the spatiotemporal frame of our study, the selection of the *kdr-e* mutation in  
592 the vector population was more likely due to insecticides used in public health than pesticides used  
593 in agriculture.** In Burkina Faso, pesticides are widely used for cotton and sugar cane (Ouedraogo et al., 2011),  
594 but only in lesser proportions in market gardening and cereal production (maize and rice are the only cereals  
595 that are treated to a significant extent (MERSI et al., 2016)). Here, in the 2-km wide buffer zones around our  
596 collection points crops occupied up to 40 % of the total land, but were mainly made of leguminous crops, millet,  
597 sorghum, with cotton and rice being only marginally present. Hence, pesticides are likely not much used (field  
598 surveys regarding the use of pesticides by the farmers could confirm this hypothesis). This could explain the  
599 absence of association between target-site mutations and the crops-related variables. Noteworthy, the fact that  
600 there was no increase in the probability of collecting an *An. gambiae* s.l. carrying a *kdr-e* resistant allele 12  
601 months post-LLIN distribution, as indicated by the RF model, could be attributed to a potential decrease in  
602 LLIN insecticidal efficacy after this period (Tan et al., 2016), resulting in lower selection pressure. Finally, the  
603 *kdr-w* and *ace-1* mutations did not increase significantly with the time since LLIN distribution. The absence of  
604 increase of the *kdr-w* mutation may be explained by its very high baseline allelic frequencies; while that of the  
605 *ace-1* mutation may be explained by the type of insecticide used to impregnate the LLINs - deltamethrin, which  
606 does not select the *ace-1* mutation.

607  
608 The statistical models captured many associations between the likelihood of collecting a physiologically  
609 resistant *Anopheles* and the variables encoding weather, both during the month preceding collection and  
610 at the hour of collection. These associations could traduce **biological costs/advantages associated with  
611 target-site mutations, both in terms of fitness and activity**, as found elsewhere for other mosquito species  
612 (Kliot and Ghanim, 2012). Regarding fitness, we found that the likelihood of collecting a host-seeking mosquito  
613 (*An. gambiae* s.s. or *An. coluzzii*) carrying a mutated allele, overall, decreased (to varying extents depending  
614 on the species and mutation) when diurnal or nocturnal temperatures during the month preceding collection  
615 got higher, i.e. in the hottest periods of the year (corresponding to the months of March-April). Carrying a  
616 *kdr* mutation might be associated with a decreased propensity to locate optimal temperatures, potentially  
617 resulting in a decreased longevity, fecundity, or ovarian development rates (Foster et al., 2003). Regarding  
618 activity, we observed that the likelihood of collecting a mosquito carrying a mutated allele (for the *kdr-e*  
619 mutation) decreased when atmospheric pressure, humidity, or temperature at the hour of collection got lower  
620; implying that mosquitoes carrying the *kdr-e* mutation could be less active in colder or drier conditions, or  
621 when atmospheric pressure is lower. Noteworthy, our results could also be interpreted in terms of fitness  
622 advantages instead of fitness costs: for instance, some studies have highlighted fitness advantages (e.g. for  
623 longevity) of the *kdr-w* mutation in *An. gambiae* s.l. in laboratory conditions (Alout et al., 2016; Medjigbodo,  
624 Djogbénou, et al., 2021).

625  
626 We also found interactions between some target-site mutations. Indeed, as the *kdr-e* and *kdr-w* are  
627 mutations of the same base pair, the allelic frequency of the *kdr-e* mutation was negatively correlated  
628 with the allelic frequency of the *kdr-w* mutation in both *An. gambiae* s.s. and *An. coluzzii*. We also  
629 found a positive relationship between the allelic frequencies of the *Ace-1* and *kdr-w* mutations in *An.*

630 *gambiae* s.s.\* This is consistent with laboratory observations in \*Culex Quinquefasciatus\* and \*An. gambiae  
631 s.s.\* showing that the cost of the \*Ace-1\* mutation is reduced in presence of the *kdr* mutation (Assogba et al.,  
632 2014; Berticat et al., 2008; Medjigbodo, Sonounameto, et al., 2021).

633  
634 Lastly, we observed that the allelic frequencies of the target-site mutations, within each vector species and  
635 for each mutation, were overall quite stable across the villages and seasons within the spatiotemporal frame  
636 of the study. At larger spatial and temporal scales, physiological resistances were found more heterogeneous  
637 (Moyes et al., 2020). In our study, such homogeneity might be due to a relative homogeneity in space and  
638 time of the main determinants of physiological resistance (access and use of insecticide-based vector control  
639 interventions). The quite stable rates of physiological resistance throughout the seasons might traduce the  
640 fact that the possible fitness costs/advantages are likely rather limited, within the range of meteorological  
641 conditions in our area.

## 642 Behavioural resistance phenotypes: potential drivers and spatiotemporal heterogene- 643 ity

644 An important and pending question is the genetic (constitutive) or plastic (inducible) nature of behavioural  
645 resistances (see Introduction). In this study, we found no statistically significant association between any of  
646 the indicators of behavioural resistance phenotypes and neither the time since LLIN distribution nor the VC  
647 tool implemented. There was hence no evidence of growing frequencies of behavioural resistances (exophagy,  
648 early- and late-biting) in response to vector control within the 1.25 to 1.5 years of this study, i.e. **no clear  
649 indication of constitutive resistance.**

650  
651 Nonetheless, comparison of the exophagic phenotype rates found here with those of previous studies in  
652 the same countries, suggests that there may still be a genetic component to mosquito foraging behaviour.  
653 Indeed, the exophagy rates measured here tended to be higher than those historically reported for these  
654 species. For example, a recent review of *An. gambiae* s.l. \textcolor{LimeGreen}{biting behaviour from a range  
655 of African countries between 2000 and 2018 concluded that during this time period, ~ 80% of the vectors bite  
656 occurred indoor (all countries included) and in particular ~ 75% in Burkina Faso} (Sherrard-Smith et al., 2019)  
657 \textcolor{LimeGreen}{(hence respectively ~ 20% and 25% outdoor). Here we measured substantially higher  
658 levels of exophagy : 44% (range ~ 18-56%) in the Diébougou (BF) area and 56% (44–60%) in the Korhogo (IC)  
659 area. Other recent studies, contemporaneous to ours, have found relatively high levels of exophagy for *An.  
660 gambiae* s.l. in rural areas, e.g. 54% in southwestern Burkina Faso} (Sanou et al., 2021) \textcolor{LimeGreen}{or  
661 55% in Ivory Coast (Assouho et al., 2020). Such high levels of outdoor biting, in comparison with past levels,  
662 suggest that behavioural adaptations may be ongoing in the study areas, most probably in response to the  
663 widespread and prolonged use of insecticide-based vector control tools.}}

664  
665 We also found many statistically significant associations between the likelihood of collecting a behaviourally  
666 resistant phenotype and the meteorological conditions during the month preceding collection. This might  
667 indicate that these phenotypes could be induced by past environmental conditions, acting at the adult or larval  
668 stage, or through paternal/maternal effect. Such relationships between environmental condition at the larval  
669 stage and adult behaviour have indeed been observed in other insects [Müller et al. (2016), and ref cited in].

670  
671 The hypothesis of a hereditary component in the behaviour of malaria vectors (at least for the biting  
672 hour) is supported by a recent study which has observed, for *Anopheles arabiensis* in Tanzania, that F2 from  
673 early-biting F0 (grandmothers) were - to some extent - more likely to bite early than F2 from mid or late-biting  
674 F0 (Govella et al., 2023). Under this hypothesis, the relationship between the prevalence of behaviourally  
675 resistant phenotypes and the meteorological conditions during the month preceding collection could indicate  
676 a cost/advantage, at the adult, larval or both stages, of their associated genotypes.

677

678 In our study, the absence of significant association between the probability of behavioural resistances and  
679 insecticide-related variables might be due to the relatively short length of the study (2 years). In a similar study  
680 conducted in another region of Burkina Faso over a two-year period as well, researchers recorded, as we have,  
681 no changes in the biting behaviour of *Anopheles gambiae* s.l.\*, including early biting, exophagy, and exophily,  
682 throughout the duration of the study (Sanou et al., 2021). Although resistance phenotypes can emerge in this  
683 time frame (Moiroux, Gomez, et al., 2012), a recent (almost) 4-years-study in Tanzania (Kreppel et al., 2020)  
684 detected shifts in vector behaviour (i.e. increased rate of exophily for *An. arabiensis*\* and *An. funestus*\*)  
685 that could be obscured in shorter-term surveys, in agreement with the hypothesis that mosquito behaviours  
686 are likely complex multigenic traits (Main et al., 2016) and might therefore respond slowly to selection (at  
687 least, slower than target-site mutations, which are linked to single genes and may hence respond rapidly  
688 and efficiently to selection). Anyhow, the results of these various longitudinal studies suggest that long-term  
689 monitoring of vector behaviour (> 2 years), particularly in areas with a long history of use of insecticides in  
690 public health, is critical to better understand the biological mechanisms underlying behavioural resistances,  
691 to potentially assess their development rate, and more broadly to assess residual malaria transmission risk  
692 (Durnez and Coosemans, 2013; Kreppel et al., 2020; Sanou et al., 2021).

693

694 Weather can impact the fitness of possible genotypes associated with behavioural resistant phenotypes,  
695 but may also directly influence the time and location of foraging activity (see Introduction for more details).  
696 Here, we found many associations between mosquito host-seeking behaviour and variables representing  
697 meteorological conditions on the day or at the hour of collection. For instance, the probability for an *An.*  
698 *gambiae* s.s. to be collected outdoor in the Korhogo area increased when the air indoor was dry, or when  
699 the air outdoor became relatively more humid than indoor. Likewise, in the Diébougou area, the probability  
700 for an *An. funestus* to be collected outdoor increased when the air outdoor became relatively cooler than  
701 indoor. These observations are consistent with the hypothesis of mosquitoes shifting from indoor to outdoor  
702 host-seeking in case of desiccation-related mortality risk indoors, as observed and discussed elsewhere (Kessler  
703 and Guerin, 2008; Kreppel et al., 2020; Ngowo et al., 2017). The meteorological conditions seemed to cause  
704 not only spatial, but also temporal shifts in host-seeking activity. For instance, we found that the probability  
705 of collecting a late-biting *An. gambiae* s.s. in the Korhogo area increased when the nocturnal temperature  
706 increased. Several associations also suggest that some malaria vectors may modify their behaviour in response  
707 to environmental variation that reduces host availability, as hypothesized elsewhere (Durnez and Coosemans,  
708 2013). For instance, the likelihood of collecting an *An. gambiae* s.s. (in the Korhogo area) or an *An. funestus* (in  
709 the BF area) outdoor increased at hours when people were protected by their LLINs. Likewise, the likelihood of  
710 collecting an early-biting *An. gambiae* s.s. in the Korhogo area increased when the % of LLIN users in the village  
711 increased. Altogether, all these associations suggest that in our study areas **mosquito foraging behaviour**  
712 **is driven - to a certain extent - by environmental conditions at the time of foraging activity**, i.e. that  
713 vectors likely modify their time or place of biting according to climatic conditions or host availability. The many  
714 associations that were captured here in field conditions could be further tested experimentally, to quantify  
715 their effect more precisely and validate the underlying biological hypothesis.

716

717 Although many significant associations between environmental parameters and foraging behaviours have  
718 been captured by the models, their explanatory and predictive powers were overall weak. A low explanatory  
719 power can indicate either i) that variations in the dependent variable (here, individual vector resistance) are  
720 only marginally caused by the independent variables or ii) that the statistical model does not capture properly  
721 the true nature of the underlying relationships between the studied effect and its drivers (Karpatne et al.,  
722 2017) (e.g. a linear regression cannot, by definition, capture non-linear relationships that might exist in nature).  
723 Here, we minimized the risk of omitting important, complex associations by using, **complementarily** to the  
724 binomial regression model, a machine-learning model (namely a random forest) that is inherently able to

725 capture complex patterns contained in the data **if any** (e.g. non-linear relationships, interactions) (Breiman,  
726 2001a). Still, the models had low predictive powers. Altogether, these results indicate that very likely, despite  
727 the amount, granularity and diversity of potential factors measured and introduced in the models, most of the  
728 factors driving the individual host-seeking behaviours of the mosquitoes were not introduced in the models.  
729 Another possibility could be that some of our independent variables did not represent the actual “reality” in the  
730 field (e.g. the distance to the nearest stream is not necessary an ideal proxy for the distance to the breeding  
731 site). Nevertheless, since we used a wide range of variables encoding the environmental conditions at the time  
732 of foraging activity, we can hypothesize that within the spatiotemporal frame of the study, **mosquito foraging**  
733 **behaviour was only marginally driven by environmental variations**. This leaves the floor to other factors,  
734 like genetics (see above), learning, or randomness.

735  
736 To test whether physiological resistance impacts the behaviour of host-seeking mosquitoes, we introduced  
737 in the behaviour resistance models of *An. coluzzii* and *An. gambiae s.s.* in the Diébougou area two variables  
738 encoding the genotypes for respectively the *kdr-w* and *kdr-e* mutations. No statistically significant associa-  
739 tion was found. In other words, **we could not find, in the field, a behavioural phenotype (among those**  
740 **studied, i.e. exophagy, early- and late-biting) associated with a genotype for one of the target-site mu-**  
741 **tations**. The only study, to our knowledge, having investigated the relationship between the *kdr* mutation  
742 and biting time or location in the field has also reported no statistically significant association between these  
743 two mechanisms of resistance to insecticide (Djènotin, Bouraima, et al., 2021). Noteworthy, in our study,  
744 there was few variabilities in the genotypes of the collected mosquitoes (i.e. few homozygote susceptible  
745 mosquitoes captured, particularly for the *kdr-w* mutation), making it unfavorable to detect associations between  
746 physiological and behavioural resistances. In the Korhogo area, such analysis could not be performed because  
747 physiological resistance **data** was not available at the individual mosquito level.

748  
749 Finally, we observed that the behavioural resistance **phenotypes** rates for each vector species in each health  
750 district were, overall, relatively homogeneous across the villages and seasons within the spatiotemporal frame  
751 of the study (as for physiological resistances). This could mean that the overall dynamics of behavioural  
752 resistance occur at broader spatial and temporal scales than those of our study. At larger scales (i.e. among  
753 countries and across years in Africa), exophagy rates of *Anopheles* mosquitoes seem, actually, to be more  
754 variable (Sherrard-Smith et al., 2019).

## 755 **Implications of the findings for the management of vector resistance in the study** 756 **areas**

757 Long-lasting insecticidal nets have undoubtedly played a major role in reducing malaria cases throughout  
758 Africa, thanks both to their barrier and killing effects. More locally, we highlighted the efficacy of their barrier  
759 role in the Diébougou area by showing that, for their users, they prevented more than 80% of *Anopheles* bite  
760 exposure in the area (Soma, Zogo, Taconet, et al., 2021). **However, despite these successes, many studies**  
761 **strongly suggest that the insecticides they are impregnated with are responsible for the rise of physiological**  
762 **resistances in the malaria vectors susceptible populations (see Introduction). In our study, the positive and**  
763 **significant associations found between the probability to collect a physiologically resistant mosquito and**  
764 **LLIN-related variables (time since LLIN distribution, LLIN use rate) supports these findings**. We also highlighted  
765 that in response to an LLIN distribution, physiological resistance seems to grow quite rapidly in a susceptible  
766 population. Besides the **selection** of physiological resistance, comparison with historical data suggests that the  
767 vectors may also be progressively changing their feeding behaviour to avoid the effects of the insecticides -  
768 although there was no clear evidence of this in the strict context of this study. Such trends in vector resistance  
769 may have an important epidemiological impact (Sherrard-Smith et al., 2019). Altogether, these results show,  
770 if still necessary, that we urgently need to think more strategically about our use of insecticides in public  
771 health tools in our areas. Switching to alternative insecticides, rotating or mixing insecticides, using current

772 or novel insecticides in vector control tools others than long-lasting nets, entirely removing the insecticides  
773 from the vector control toolbox, or fostering the use of insecticidal-free tools, are all actions that could be  
774 envisaged (Paaijmans and Huijben, 2020). Burkina Faso has, actually, distributed LLINs that mixes pyrethroid  
775 with Piperonyl butoxide (PBO) in the last universal LLIN distribution, in 2019.

776

777 Here, we observed that both behavioural and physiological resistances of mosquitoes were quite stable  
778 across the villages and seasons within the spatiotemporal frame of the study. This contrasts with their biting  
779 rates, which was found, in another study (Taconet, Porciani, et al., 2021), highly variable across the villages,  
780 seasons, and amongst the species. This calls for distinct spatio-temporal management of interventions targeted  
781 at reducing human-vector contact and reducing resistance selection (both essential) in the field. While the  
782 former should be highly locally tailored (i.e. specific to each village and season) (Taconet, Porciani, et al., 2021),  
783 the latter, due to its stability across villages and seasons, would probably not benefit significantly from being  
784 customized at these spatio-temporal scales in our areas. In other words, while resistance management plans  
785 are undoubtedly urgently needed, there is no compelling evidence – in the current state of the knowledge –  
786 that they should be tailored at very fine scales (village, season). Noteworthy, mosquitoes were collected during  
787 the dry season and at the beginning and end of the rainy season, but, for logistical reasons, not at the peak of  
788 the rainy season (and therefore not at the likely peak of mosquito abundance). It would be worth collecting  
789 mosquitoes at this season to confirm the observed resistance rates.

## 790 Conclusion

791 In an attempt to better understand the drivers of the intensity and spatio-temporal heterogeneity of physio-  
792 logical (genotypes) and behavioural (phenotypes) resistance in malaria vectors, at the scale of a rural health  
793 district over a period of 1.5 years, we have mainly (i) shown that resistance (both physiological and behavioural)  
794 was quite homogeneous across the villages and seasons at these scales, and (ii) hypothesized that at these  
795 spatiotemporal scales, vector resistance seemed to be only marginally driven by environmental factors other  
796 than those linked to insecticide use in current vector control. Following the distribution of LLINs, the rapid  
797 widespread of physiological resistance occurring in tandem with probable lower acting behavioural adaptations,  
798 are very likely contributing to the erosion of insecticide efficacy on malaria vectors. We believe that without  
799 waiting to understand precisely the underlying drivers, mechanisms, and rates of selection of resistances, the  
800 malaria control community needs to think very strategically about the use and usefulness of current and novel  
801 insecticide-based control interventions.

## 802 Acknowledgements

803 We thank populations of the villages for their kind support and collaboration. We also thank all the field and  
804 laboratory staff for their strong commitment to the REACT project.

## 805 Abbreviations

806 AIC: Akaike Information Criterion; AUC: Area under the ROC Curve; BF: Burkina Faso; CV: Cross-Validation;  
807 GLMM: Generalized Linear binomial Mixed-effect Model; GPM: Global Precipitation Measurement; HLC: Human  
808 Landing Catch; IC: Ivory Coast; IRS: Indoor Residual Spraying; LLIN: Long Lasting Insecticide Nets; ML: Machine

## 812 **Data, scripts, code and supplementary information availability**

813 **Data and scripts** are available online: <https://doi.org/10.23708/LV8GEW> (Taconet, D Soma, et al., 2023a)

814 **Supplementary information** are available online: <https://doi.org/10.23708/VJEEMU> (Taconet, D Soma, et al.,  
815 2023b)

## 816 **Ethics approval and consent to participate**

817 Ethical clearance for the study was granted by the National ethics committee (No. 063/MSHP/CNER-kp) in  
818 Côte d'Ivoire and by the Institutional Ethics Committee of the Institut de Recherche en Sciences de la Santé  
819 (No. A06/2016/CEIRES) in Bukina Faso. We received community agreement before the beginning of the study,  
820 and we obtained written informed consent from all the mosquito collectors and supervisors. Yellow fever  
821 vaccines were administered to all the field staff. Collectors were treated free of charge when they were  
822 diagnosed with malaria during the study period according to WHO recommendations. They were also free to  
823 withdraw from the study at any time without any consequences.

## 824 **Conflicts of interest disclosure**

825 The authors declare that they comply with the PCI rule of having no financial conflicts of interest in relation to  
826 the content of the article. Nicolas Moiroux, Frédéric Simard and Cédric Pennetier are recommenders for PCI  
827 Zoology.

## 828 **Funding**

829 This work was part of the REACT project funded by the French Initiative 5%—Expertise France (no. 15SANIN213),  
830 and the ANORHYTHM project funded by the French National Research Agency (no. ANR-16-CE35-008). The  
831 funders had no role in study design, data collection and analysis, decision to publish, or preparation of the  
832 manuscript. PT was supported by the French Institute of Research for Sustainable Development (IRD) through  
833 an international volunteer fellowship.
